Cold Weather Accessories for Motorists

Garage Heaters, Foot Warmers, Electric Mixture Heaters and Primers All Valuable to Winter Drivers

WITH the coming of Winter the automobilist naturally desires to fortify himself and the car against the ravages of the freezing weather. There are five kinds of heaters which he may use: the garage heater, which may be an ordinary stove or furnace, or a special gas heater of compact design built for the purpose; the electric mixture heater to insure easy starting; the radiator heater to prevent freezing; the foot warmer or car heater; the hand warmer.

Scientific Safety Garage Heater—A heater, Fig. 1, using gas as fuel and which will not set fire to inflammable vapors in the atmosphere, is made by the Scientific Heater Co., 1075 Power avenue, Cleveland, O. The device is made in three sizes: for garages 18 by 20 feet, 22 by 26 feet, and 26 by 36 feet. The respective prices are $25, $32.50 and $45. A larger garage may be heated by installing additional heaters.

A small pilot light just below the door of the heater is lighted during the first cold days of the season, and this becomes the control, no more matches being necessary.

Superior Safe Garage Heater—A garage heater made by the Superior Mfg. Co., N. S. Pittsburgh, Pa., and which operates on gas is shown in Fig. 2. It consists of a small furnace and a tubular radiator inside a heavy galvanized casing, the outside side dimensions of which are: length, 40; height, 33, and width, 12 inches. It is stated that the combustion chamber is so arranged that the gas is completely burned and none is wasted. Safety is secured by completely inclosing the combustion chamber from the outside air. The air to the heater is brought from outside the building through a suitable pipe and the burned gases are exhausted through a chimney pipe. The heater is lit at the beginning of the season and after that a small pilot light is kept burning continuously so that the heat may be turned on at any time afterwards without running the risk of lighting a match. The price is $25, f.o.b. Pittsburgh.

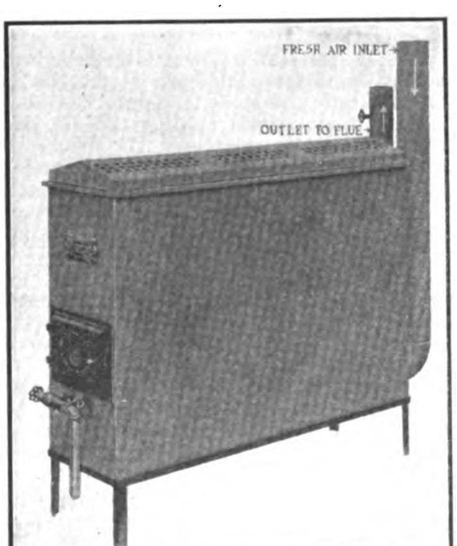

Fig. 2—Superior Safe garage heater

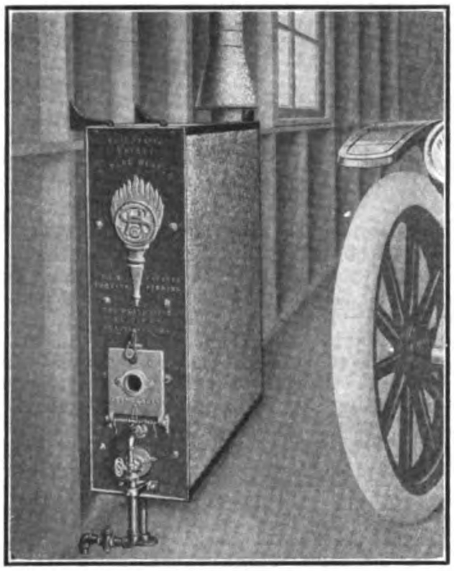

Fig. 1—Scientific Safety garage heater

Lehman Heater—A special form of coal is used in the heater shown in Fig. 3. This heater is made in various sizes and styles, and is offered at prices ranging from $1.75 to $10. As the heat comes from within and is not derived from the exhaust or cooling system, these foot warmers are easily portable and may be carried from one car to another. The fuel is made up into briquettes and is introduced into the heater by putting it into a drawer.

This heater is made by Lehman Bros., 10 Bond street, New York City.

Samson Foot Warmer—The American Electric Co., State and Sixty-fourth streets, Chicago, Ill., is manufacturing a foot warmer, Fig. 5, which uses a special form of fuel.

The device is easily portable. It is fireproof and the products of combustion are odorless. One filling of fuel will supply heat for over 6 hours. The warmer cannot be tipped over, and is provided with a handle for convenient carrying. The price is $4.50, and the fuel bricquettes sell for 50 cents per dozen.

Clark Heater—A carbon-burning foot warmer, is manufactured by the Chicago Flexible Shaft Co., Chicago, Ill. Briquettes of specially prepared coal which last from 12 to 16 hours are used. The heaters are miniature metal stoves. Each consists of a strongly reinforced oval or triangular metal case, solidly riveted. This is lined with asbestos and then covered with a carpet. A sliding metal drawer held in place by a strong spring contains the fuel. The heat is regulated by a damper in the front. The prices of the heaters vary from $1.75 to $10. A dozen bricks sell for 75 cents.

Lytle Auto Heater—The installation of the exhaust tonneau heater made by the Lytle Auto Heater Co., Memphis, Tenn., is shown in Fig. 4. A flexible steel tube 1 inch in diameter taps the exhaust pipe just before entering the muffler, and by-passes the gas through the passages in the heater, and from thence to the open air. Air flows from under the car up around these heated passages and is warmed, thus supplying heat to the passengers.

K. P. Foot-Rest Heater—An exhaust heater which takes the place of the foot rest, is made by the K. P. Foot Rest Heater Motor Mart, Park Square, Boston.

Its construction is clearly shown, the heat being taken from the exhaust pipe, passed through the heater and finally into the air. The heat is regulated by a valve at one end. The device is finished in nickel, brass, or is oxidized, and it is furnished in lengths to fit any car. It sells for $25, including all parts for attaching.

American Auto Heater—Another exhaust heater which is placed in the floor of the car is made by the American Auto Heater Co., 160 Fourteenth street, Buffalo, N. Y. It is made of aluminum and is 10 inches square by 3 inches deep. It sells for $28.50.

Radio Auto Heater—An exhaust heater of simple design is made by the Milwaukee Auto Specialty Co., 715 Chestnut street, Milwaukee, Wis. It is designed to be countersunk in the floor and consists of a hollow casting inclosed in a sheet metal box which measures 14.5

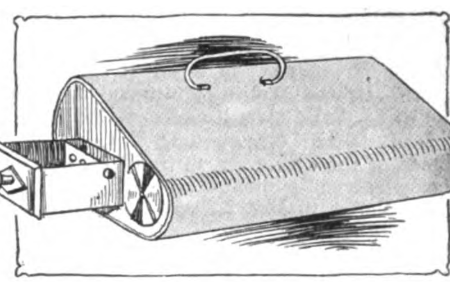

Fig. 3—Lehman foot warmer. It burns a special coal

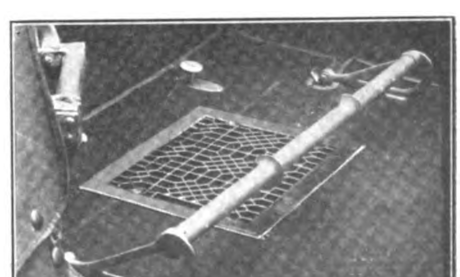

Fig. 4—Lytle Auto Heater

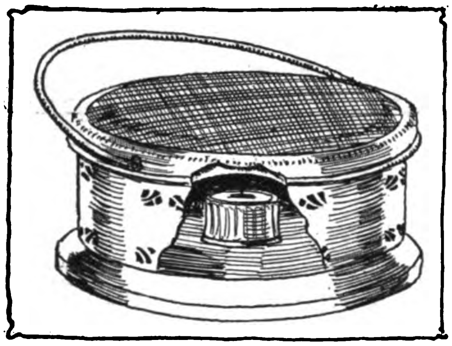

Fig. 5—Samson foot warmer

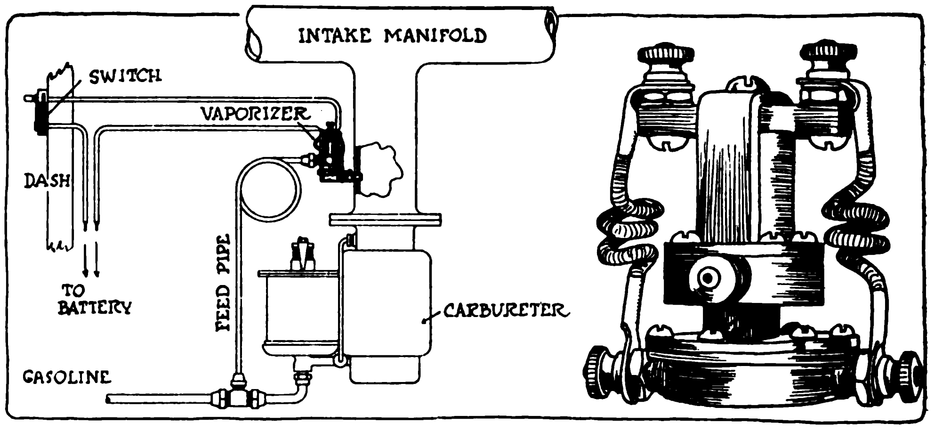

Fig. 6—Sure-start electric vaporizer. Left—Complete diagram showing connections. Right—vaporizer itself

by 5 by 3 inches. The top of the radiator has a grilled, nickel-plated surface. The heat is regulated by a lever that actuates a three-way valve in the branch from the exhaust pipe.

Consolidated Heater—A small electric heater that does away with the necessity of draining the water from the radiator when the car is left in an unheated garage is being advanced by the Consolidated Car Heating Co., Singer Tower, New York City. This heater is placed on the top of the cylinders, the hood put down and the current switched on. Sufficient heat is generated to keep the mechanism inside the bonnet warm, prevent freezing and make starting easy. The necessary current may be obtained from an ordinary lamp socket and the cost of operating is 1 cent per hour. Alternating or direct current at 110 volts can be used. The price complete with attaching plug is $7.50.

Sure-Start Electric Vaporizer—The Sure-Start Electric Vaporizer, Fig. 6, is a device which supplies hot gasoline vapor to the intake manifold, thus insuring easy starting in the coldest weather. It is independent of the carbureter. A small switch on the dash controls both the supply of gasoline and the electric current, which requires a 6-volt battery. When the switch is turned on, the suction of the motor draws the fuel through the heated portion of the device, vaporizing the fuel. The gasoline feed may be either gravity or pressure.

It is stated that the device may be installed in less than an hour by any ordinary mechanic. The diagram of connections is clearly illustrated. The price of the device is $8, and it is made by the United Motor Equipment Co., 19 South La Salle street, Chicago, Ill.

Ieco Hand Warmers—To keep the hands of the driver warm in cold weather the electrically heated steering wheel grips shown in Fig. 7, have been brought out by the Interstate Electric Co., New Orleans, La. The grips are covered with leather, laced on. Under the leather of each grip are two copper plates between which is a coil of wire. Current for these grips may be supplied from the lighting system or, in the case of the Ford, from the magneto. It is stated that the grips only consume 18 watts.

Ieco Manifold Plug—This concern also offers a manifold plug, Fig. 8, which makes starting easy by warming up the charge as it passes to the cylinders. In addition it performs the ordinary functions of a primer by admitting auxiliary air to the manifold at high speeds. Gasoline may be introduced through it for starting, and kerosene or alcohol for removing carbon from the cylinders. It is made in 6 and 12-volt styles and sells for $5.

Neverout Radiator Heater—With the idea of obviating the danger of a freeze-up and at the same time making starting easy, without installing a complete garage heating system, the Rose Mfg. Co., 910 Arch street, Philadelphia, Pa., has designed a radiator heater suitable for any car. It can be quickly attached to the cooling system when the car comes in at night. It consists of a small hot water heater, which is operated from the city gas or electric light mains, the device being furnished with either type of heater.

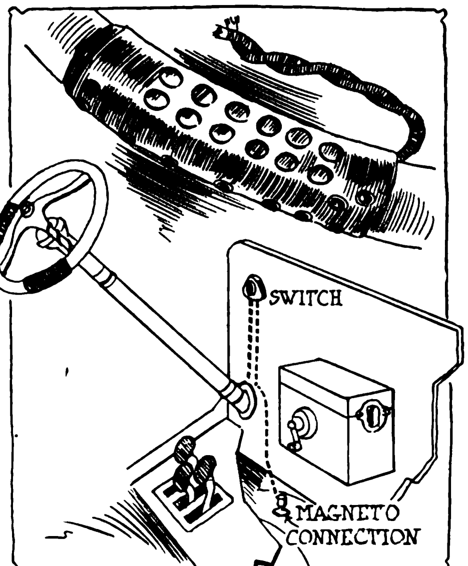

Fig. 7—Ieco hand warmers showing connections

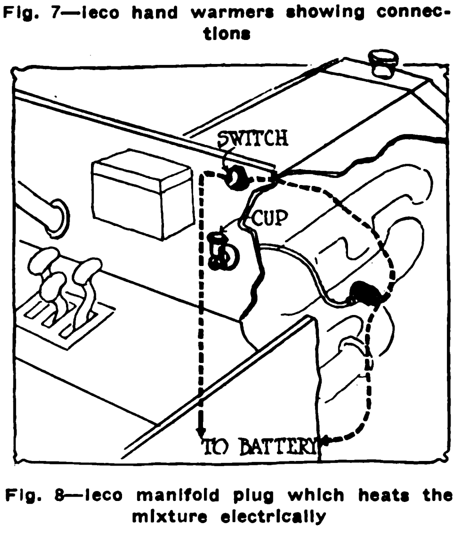

Fig. 8—Ieco manifold plug which heats the mixture electrically

The heater warms the water, which passes up from it into the top of the radiator. The return connection to the heater is through a small rubber tube which may be attached to the drain cock at the bottom of the radiator. Circulation is automatic because the heated water, being lighter, rises, and the colder water rushes in to take its place.

Victory Primer Pump—A priming pump for introducing a vaporized fuel to the manifold for starting motors in cold weather or for priming motors that are hard to start is shown in Fig. 13. The pump consists of a cylinder .625 inch diameter by 5 inches length.

The pump is designed to be fastened to the dash or heel board by screws. A connection is made from the pump to the gasoline pipe line by brass tubing, and from the pump to the intake manifold.

It is put out by the Perkins Appliance Co., Springfield, Mass.

Warm Hand Wheel—A steering wheel, Fig. 9, with electrically heated grips is made by the Warm Hand Steering Wheel Corp., Poughkeepsie, N. Y. The wheel is slightly countersunk at each side so as to allow the tubing forming the heater to be wound flush with the balance of the rim. In the tubing is a heavily-insulated wire, one end of which runs to the current source while the other is grounded on one of the spider arms. The necessary electric energy may be obtained from a storage battery, lighting generator or Ford magneto.

The Warm Hand Wheel is installed on a Ford or any machine where the rim is screwed onto the spider by simply removing the four screws holding the old rim and putting on the new. On machines where the rim is integral with the spokes the whole wheel is furnished.

Chi-Fau-Co Primer—Fuel injection into the manifold is accomplished by means of a hand-operated plunger pump mounted horizontally on the dash in the primer, Fig. 11, made by the Chicago Faucet Co., 313 South Clinton street, Chicago, Ill. By reciprocating the pump plunger, the fuel is first sucked from the main fuel line and then forced into the manifold. The price of the device is $6 and when arranged to draw gasoline from a separate reservoir, the price complete is $6.50.

Injex Primer—The Reflex Ignition Co., 211 High avenue, Cleveland, O., has brought out the primer shown in Fig. 11 for $2.50.

By pulling a ring on the steering post

Vol. XXXI — New York—Thursday, December 10, 1914—Chicago — No. 24

The Automobile

War Stops Olympia, But Not Car Development

Automobile Industry in England Shows Marked Trends in Spite of Interruption in Buying—Light Fours the Feature—Sixes Hold Their Own

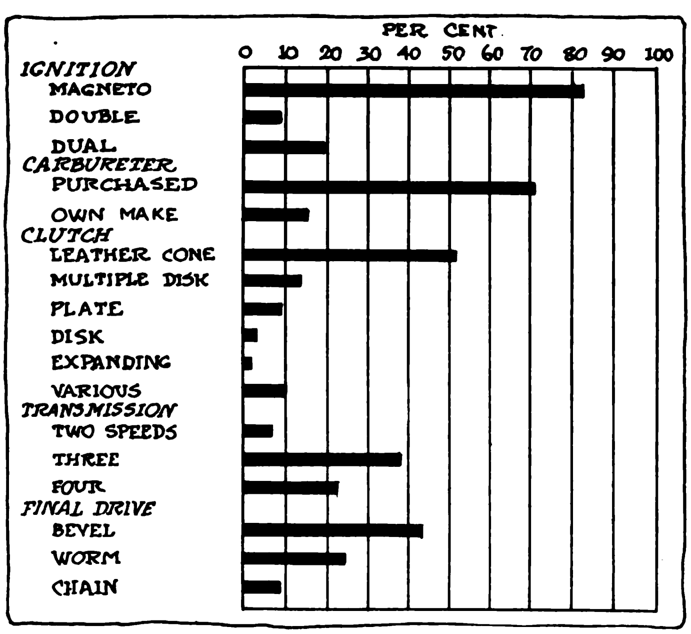
By J. Edward Schipper

THERE is no Olympia show this year in London. The Gods of War have so ordered. Yet this dictum cannot stop entirely the wheels of progress and thought. We still turn toward Olympia and, though war has laid its staying hand upon the exposition, nevertheless, the 1915 announcements of the English factories show that cardinal trends would have been brought out by the show. When war was declared, the plans of the designers were already well formulated and the 1915 test chassis were on the road. Consequently there has been little falling off in the number of announcements for the new season, and as far as the engineering development of the industry is concerned, there has been no interruption in progress.

More Small Cars

Most important is the increase of the number of small cars listed in the neighborhood of $875. The Ford in Great Britain sells for $610, which will give a comparative idea of the prices of the small British products. A number of the small cars are developments of the cyclecar movement of the past 2 years. These cars are now miniature automobiles built along the same lines as the larger cars, with a standard tread but with shorter wheelbase and generally smaller lines. The upholstery and equipment are as luxurious as on the larger cars, extreme lightness in the power plant and structural work providing maximum economy.

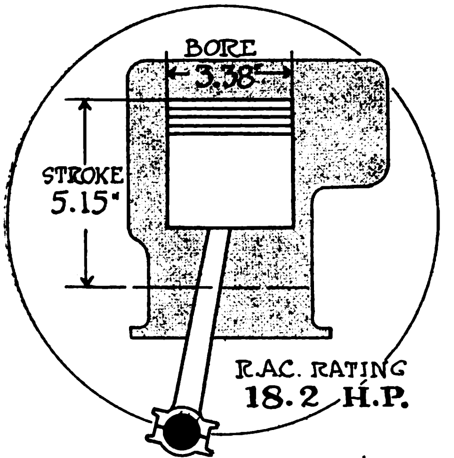
These small cars have a piston displacement averaging close to 65 cubic inches. The bore ranges from 60 to 70 millimeters, or 2.36 to 2.75 inches, with a stroke approximating 3 inches. Makers, who have had cars in this field before, are endeavoring to secure more power for a given piston displacement. The result has been an increase in the valve sizes and in the compression. Throughout the entire light car practice the manufacturer is endeavoring to get as much power as he can from an engine that will give him the maximum fuel economy. The result is that the little machine is apt to be somewhat overloaded with the fully equipped body.



Predominating features of British cars may be mentionad as magneto ignition, cone clutches and bevel drive. The percentage of three-speed gearset is not greatly in excess of four-speed types

Sell Cars Equipped

Still another tendency is that of selling the car with full equipment. In this respect the British manufacturers are following the American lead, as well as the example set by Renault a year ago in France. We now find it customary for British cars



AVERAGE PRICE OF CAR $2000

The average British car would sell for $2,000 and would have an R.A.C. rating of 18.2 horsepower. Dimensions would be 3.38 by 5.15

to be advertised as equipped with electric lighting and starting. Although it is not true that cars selling as low as $750 are so equipped as yet, the rapid trend in that direction indicates that if normal progress is not interfered with in the next year or 2, British cars will be fitted with the same electric equipment as the American at approximately the same price. Last year less than 15 per cent. of the exhibitors at Olympia had electric starters, but were a show held this year the percentage would approximate 40.

Thermo-syphon cooling is used on 90 per cent. of the cars having a piston displacement of 200 cubic inches or less. Above this displacement the pump system of cooling is used on more than 50 per cent. of the motors. In British practice, as in American, there has been a growing tendency towards increasing the volume of water surrounding the cylinders, and large jacket spaces are the rule for even the smallest motor.

Electric lighting is found on practically every car marketed as low as $975. In some instances acetylene headlights are supplied with electric lamps for the side and tail; in the latter case a storage battery is used.

In general the tendencies of design are but continuations of those noted last season. The body maker in his efforts to meet the fashions of the day in coach work has made changes which stand out more prominently than any of those of a mechanical nature. The efforts to meet American competition in the low-priced car have been continued, and as a result the fully equipped, small four-cylinder car at a modern price is becoming rapidly the biggest factor in British automobile engineering.

The numerous small models produced on every hand last season by the well-known manufacturers have been continued, and in addition many others have entered the ranks. Those who built cars rated as low as 7 horsepower for 1914 have in many instances increased the size of the motor and altered various features of design to bring the car up to a rating of 10 or 12 horsepower.

Some Two-Cylinder Types

The two-cylinder car which lost considerable ground in 1914 has lost more for this season, although several concerns such as Aldays, Enfield, Gordon, etc., still continue its manufacture.

Using Stock Parts

In analyzing the changes made for 1915 it is necessary to go deeply into the minor features of the cars, but there are a few marked trends in such features as ignition, cooling, etc.

SINGLE MAGNETO IGNITION IS EMPLOYED ON NEARLY 85 PER CENT. OF THE CARS MARKETED IN GREAT BRITAIN.

THE TENDENCY NOTED THIS YEAR ON THE PART OF THE MAKERS TO USE CARBURETERS MADE BY SPECIALISTS, INSTEAD OF THEIR OWN, HAS BEEN CONTINUED. WHILE SEVERAL OFFER OPTIONAL MAKES, FULLY 85 PER CENT. PROVIDE THEIR CARS WITH CARBURETERS MADE BY MANUFACTURERS WHO ARE ONLY IN THIS FIELD.

The movement toward worm drive is continued, and those announcing new cars are in a fair percentage of instances specifying worm drive as stock. The new Vulcan and the 11.9 Phoenix are good examples of this.

The Colonial Model

All the larger British manufacturers design their cars with an eye toward a distribution in the Colonies and foreign countries. British cars have a considerable sale in Australia, Canada, throughout Africa and in Russia, as well as South America. Requirements of these countries are different from those for home consumption. Rougher roads and steeper grades have resulted in the adoption of a colonial model in the lines of the important manufacturers. Concerns such as Argyll, Armstrong, Bell, Daimler, Napier, Sheffield-Simplex, etc., make a specialty of these models.

The colonial models have longer wheelbases, higher clearances, larger wheels and tires and bigger power plants. Throughout they are of heavier design, and while not equaling the chassis design for the English roads, in economy they are of more rugged structure with a corresponding longer life.

20 Per Cent. Are Sixes

THE SIX-CYLINDER CAR IS HOLDING ITS OWN. THE PERCENTAGE OF SIXES FOR THE BRITISH MANUFACTURERS IS NOT NEARLY SO HIGH AS IN THIS COUNTRY, WHERE APPROXIMATELY ONE-HALF THE CHASSIS ARE FITTED WITH POWER PLANTS OF THIS DESCRIPTION. OF THE CARS LISTED AS ON THE BRITISH MARKET, 20 PER CENT. ARE SIXES.

This proportion has not altered materially in the past season. It is significant that only one concern of importance has brought out a new six for this season. The specifications of the sixes that were on the market for 1914 have not changed materially, all the refinements being in the nature of body changes.

23 New Builders

In spite of the fact that only one new six is announced there are more than twenty-three new concerns which have made their appearance in the British industry. Most of these make small cars, fifteen of the twenty-three having motors that have a bore of less than 2.5 inches.

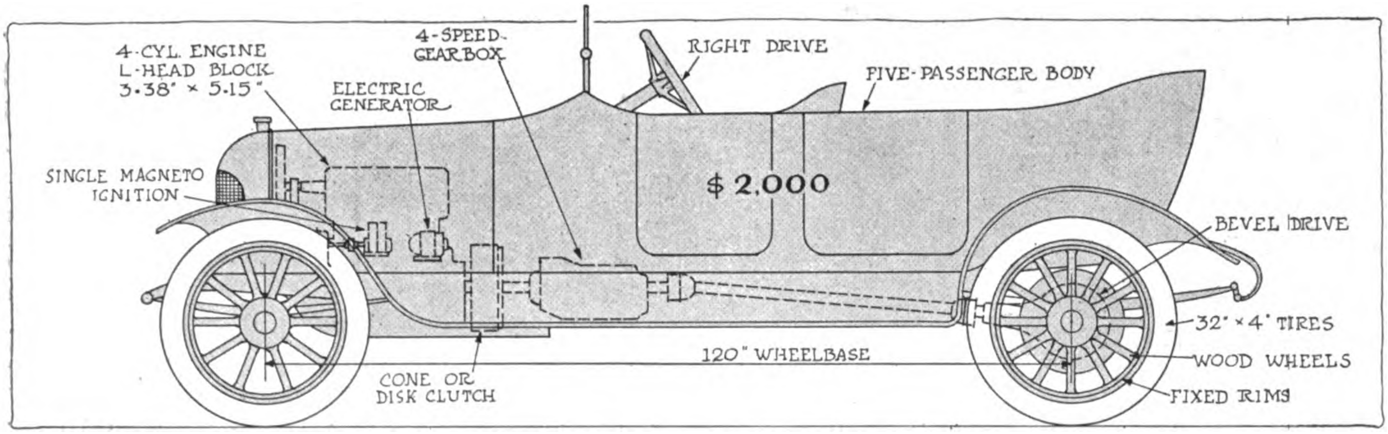
The number of concerns making cars this year has not materially increased, however, as according to the latest published reports there are fifteen who have not issued 1915 specifications. The discontinuance of the sale of Austrian and German makes in the British Isles has lessened the available supply of the larger cars, as in nearly every case cars imported from these two countries were of the heavy type with big power plants and capacious bodies.

Bodies Are Changed

Those companies that have announced their new models within the last 2 months, with very few exceptions have made their refinements in the bodies. This is not only true of the cars manufactured in the British Isles, but of those manufactured in France, which are generally announced at Olympia. The 1915 Darracq has been announced but is a direct continuation of the 1914 with the exception of body changes. The Humber has made no changes. Daimler continues to market the same two sixes and its four.

Typical British Car

Other companies have announced new models. A typical instance of a new car which brings out the trend of British industry very strongly is the Riley. It has a 2.48 by 3.46 motor with the four cylinders cast in a block. Mounted on a



The above chart is the car that would result were all the averages combined into one chassis

chassis of 96-inch wheelbase with a body of two-passenger capacity, it sells for $975. Thermo-syphon cooling, pressure-feed oiling, four-speed gearbox and 28 x 3-inch tires are used. The use of pressure-feed oiling and four-speed gearbox on a car of this size shows the strong line of demarcation between foreign and American practice.

Daimler is continuing the same lines of cars as in 1914 with the exception of improvements in the body work. Swift has a new car, bringing its line up to three chassis. The new model is a small four with a 2.48 by 3.54 motor, these dimensions being practically the same as those of the Riley. This car, while different in almost every particular, is an outgrowth of the two-cylinder light car marketed by this concern this season. The cylinders are block cast, lubrication is by pressure, and the axle a bevel gear.

New Napier Model

Napier has added to its range of models a chassis with a four-cylinder 3.5 by 5 motor. A feature of the chassis construction which illustrates a growing practice in British design is the use of tubular cross-members throughout. The engine, clutch and gearbox are in a unit power plant with three-point suspension. The cylinders are cast in pairs with the valves on the left and inclosed by a cover plate. In many respects the motor resembles American practice. The timing gears have helical teeth. Pressure lubrication is also used, and cooling is by thermo-syphon. The final drive is by an underhung worm, carried in double ball bearings with ball thrusts. The wheelbase is 124 inches.

Another well-known concern which has announced a new model is the Vulcan company. This again is an example of the low-priced car at $975 with a 2.67 by 3.93 motor. This concern has gone over to the method of incorporating the gearbox with the axle. In connection with this there is an overhead worm drive, and the tail end of the worm shaft has been selected to carry the drum for the service brake. This practice of mounting the brake drum on the rear end of the final drive shaft attracted considerable attention last year, and seems to be holding its own. An electric starting and lighting system is fitted to all the Vulcan chassis except this new model. The chain which drives the timing gears is adjustable, the magneto being carried in a brass tray, which also holds the bearings for the magneto drive pinion. By means of a screw the entire assembly can be moved to tighten the tension on the drive chain.

Star is another of the well-known manufacturers who put upon the market a new small car with a four-cylinder engine. The power plant is a 2.59 by 5 L-head block and follows the general practice of the British industry. Lubrication is by a combination splash and pressure system, cooling by thermo-syphon and the gearbox is a three-speed type.

The Calthorpe Minor is another of these small cars which, while introduced last year, has been considerably redesigned. It has motor dimensions of 2.44 by 3.54, and is a good example of how the makers have endeavored to secure more power from the small engines. The size of the valve has been increased, and also the bearing surfaces of the motor. The price of this car with acetylene head lamps and electric side and tail lights is $950.

New Wolseley Body

Wolseley has put itself on record as against the annual model idea, but from time to time changes are made as the cars are passing through the factory. A new open touring body is the latest addition. The bonnet has a slope and the cowl is of a streamline type with unbroken lines at the point of juncture to the bonnet. In the matter of equipment, a triple jointed windshield has been added and a ventilator which is the same as that used in marine work can be turned in any direction for ventilation of the forward compartment.

The Phoenix is also in the light car class, with its 2.71 by 3.93 cylinders cast in a block according to the universal practice of these small cars.

Another practice which is now common in cars of small piston displacement on the British market is the use of connecting-rods of H section.

The use of leather couplings for the magneto drive is continuing on the other side and is employed on this car. It is slotted to provide an adjustment. Another feature that is worthy of note is a detachable aluminum plate which is provided to afford access to the water-jacketing just above the exhaust manifold. A leather disk coupling is used between the clutch and the gearbox. Final drive is provided by an overhead worm, the worm wheel and the differential gear being contained in the same housing.

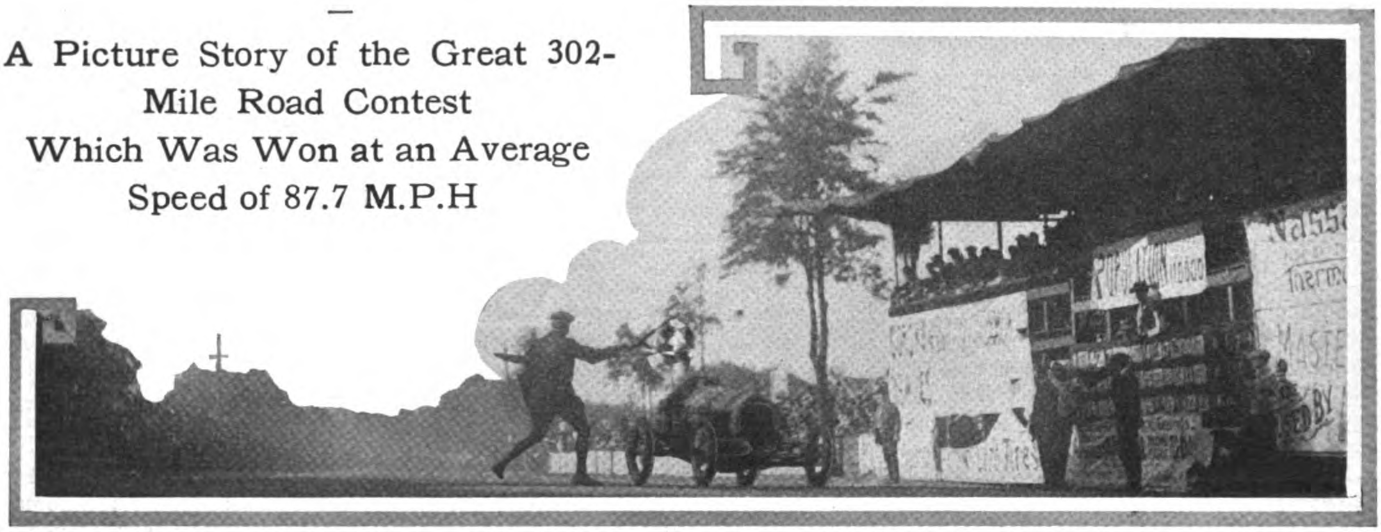
New Singer Model

A particularly good example of where a concern has developed a small car from a model which is still lighter is the Singer. The light car of last year has been discontinued and in its place a new model with a four-cylinder 3.14 by 5.10 motor. The L-head cylinders are cast in a block. American practice in the use of but two piston rings is another growing tendency on the other side and finds an example in the Singer. This motor also has an oiling system which is similar to that which is used in most American cars, the oil being taken from the reservoir in the crankcase to a dash gauge and then to the three main bearings. Oil is also fed to splash troughs which take care of the interior of the motor. Gasoline is fed by pressure from a little air-cooled pump driven by an eccentric from the camshaft.

One of the earliest concerns to announce a new 1915 model was Swift. The car is a four-cylinder 2.48 by 3.54 L-head design with the cylinders in blocks. This follows the general practice in this light class of car very closely, an interesting departure being made in placing the intake passage integral with the cylinder casting. The carbureter is bolted directly to the wall of the cylinder on the side opposite the intake valve.

Breaking the Record at Corona

A Picture Story of the Great 302-Mile Road Contest Which Was Won at an Average Speed of 87.7 M.P.H



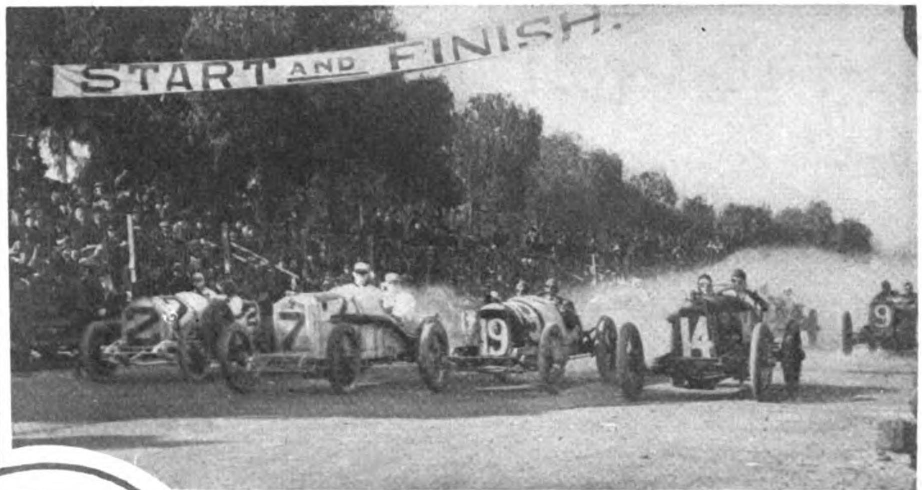
Starter Wagner giving Ed. Pullen in the Mercer the checkered flag marking the winning of the Corona race on Thanksgiving Day

A RACE in which the drivers averaged 98.6 miles per hour throughout the first thirty laps and which was finally won at an average speed of 87.7 miles per hour is bound to be of the greatest interest to every automobilist, engineer, manufacturer and dealer who takes the slightest interest in racing or in the lessons in car construction which are brought out by the gruelling grind of the road and track.

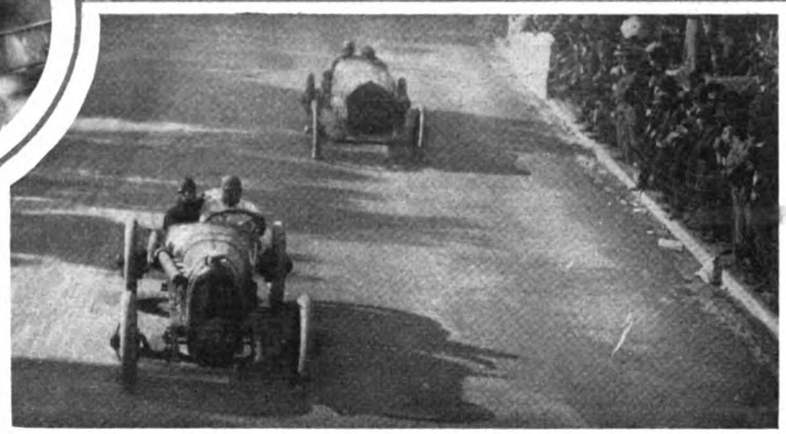
Herewith are illustrations reproduced from photographs of scenes at the great Corona Road Race held on Thanksgiving Day over a course 301.89 miles in length where the speed mentioned was attained as reported in THE AUTOMOBILE *for December 3, and where the first four drivers to finish broke the world's speedway record and the road race record as well. One of the features of the contest was the new non-stop record established by Oldfield's Maxwell, going through the entire race without making a stop of any kind.*

There were 100,000 spectators and around the course were parked 15,000 automobiles.

Cars and drivers at the starting point on the course just before the start of the 301.89-mile road race at Corona, Cal.



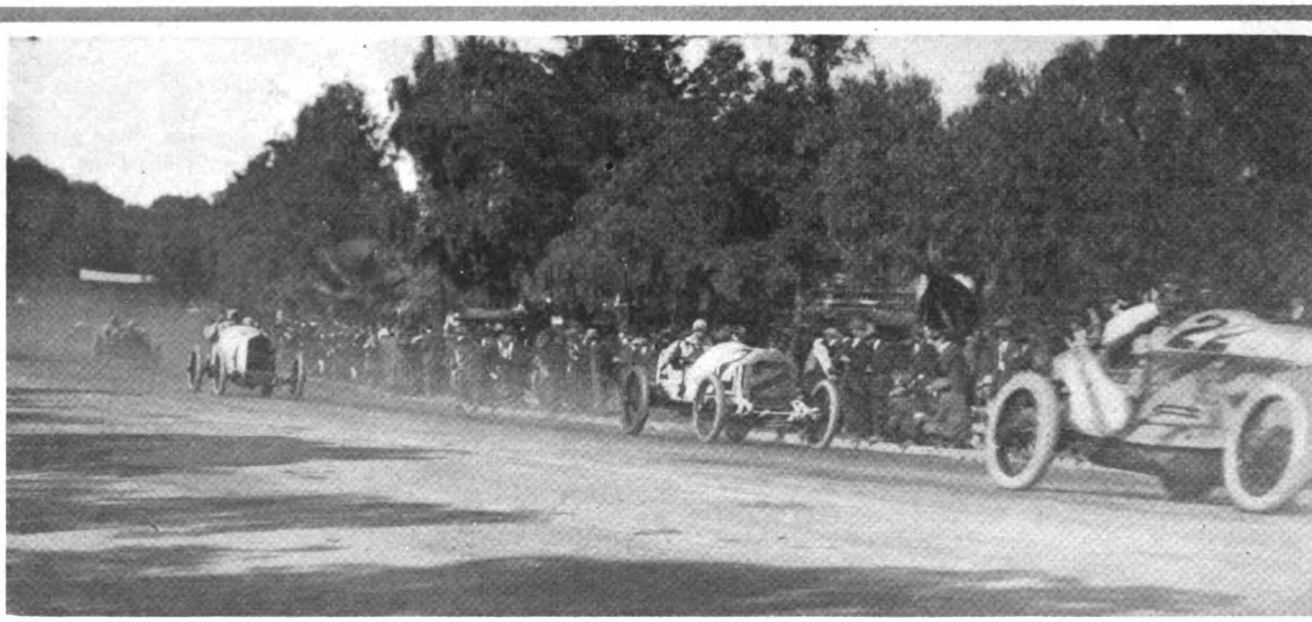
Above—The start of the 301.89-mile road race at Corona on Thanksgiving Day. Barney Oldfield's Maxwell has the pole. The flying speedway start was absolutely even



Above—George Bentel, manager of the Mercer team, signaling to Pullen on the course. Richenbacher is seen at the right of the signal board, his car having been disabled

Circle—Barney Oldfield, who finished second, establishing a new non-stop record, removes his cigar while he takes a drink of water

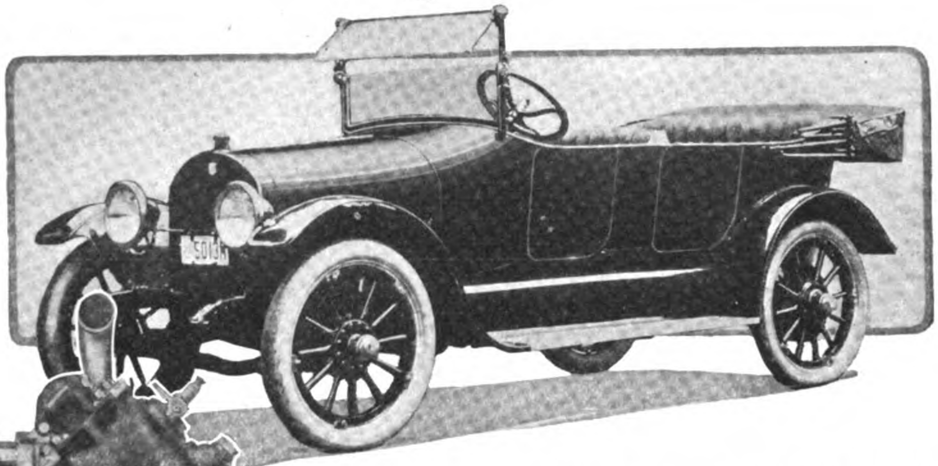
Right—Oldfield in the Maxwell passing Cadwell in the Marmon in an exciting part of the race. Oldfield, veteran of countless speed contests, admitted after the race that he never saw such a contest, the drivers circling the course like crazed demons, each carried on by the speed of the others, realizing that it was risky to do it and expecting an accident at every turn. Up to the thirtieth lap the speed average was 98.6 miles per hour. An idea of the tremendous pace maintained may be gained from the fact that the averages of the seven drivers allowed to finish varied from 87.7 to 77.2 miles per hour



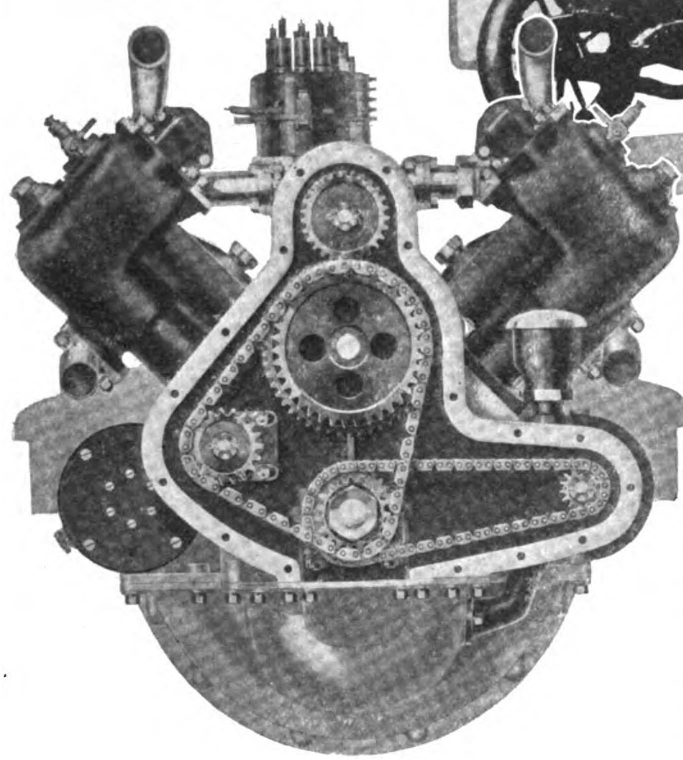
De Palma's Mercedes, Klein's Stutz, Richenbacher's Mercer and Oldfield's Maxwell in a speed brush in the tenth lap. All through the early part of the race the drivers averaged 98.6 miles per hour, rendering it intensely interesting to the 100,000 spectators

Eight-Cylinder King for $1,350

V-Type Motor 2 3-4 by 5—113-Inch Wheelbase—15 Miles per Gallon of Gasoline



Eight-cylinder five-passenger King touring car, which, with complete equipment, electric starting and lighting, etc., sells for $1,350



Front view of King V-type eight-cylinder motor with timing gear cover removed, showing silent chain drive. Note mounting of ignition distributer in center; also note compact and accessible design of motor

TO the King Motor Car Co., Detroit, Mich., goes the distinction of placing on the market the second American automobile equipped with an eight-cylinder engine. This concern has designed a remarkably compact and accessible V-type motor with cylinders 2 3-4 by 5. This is installed in a chassis of 113-inch wheelbase, and sold at $1,350 with a roomy five-passenger touring body.

It is not surprising that another eight-cylinder machine should appear, for the popularity of this type is gaining and the merits of the construction are becoming well-known. Performance is undoubtedly the eight's greatest merit, this referring not only to flexibility but to fuel consumption as well, and there is a great class of buyers which takes kindly to any type of engine that will make necessary the minimum of gearshifting no matter how simple that operation may be.

It was demonstrated to the representative of THE AUTOMOBILE that the new King will start readily from a standing position in high gear, and it can be accelerated to 35 miles an hour from a speed equivalent to a slow walking pace within half a city block. Unofficial fuel tests show that the engine will run under ordinary conditions 15 miles on a gallon.

The general chassis design does not depart from that of the four-cylinder model. The gearbox, of three-speed form, is in unit with the engine, and other specifications include a propeller shaft inclosed within a torsion tube, floating axle, 33 by 4 tires and the special form of cantilever rear springs which have always featured King cars.

In designing its eight, the King company has adhered to the usual form in that the two blocks of four cylinders are mounted at 90 degrees to each other on the crankcase with valves facing. One is impressed with the accessibility of the parts. All tappets may be readily reached for adjustment, the carbureter being practically the only thing placed in the V between the cylinder blocks. The electric cranking and lighting units are carried on opposite sides of the crankcase, and the ignition distributer is mounted at the front of the space between and out of the way.

The stroke, 5 inches, is nearly twice the bore, 2 3-4 inches. The exact stroke-bore ratio is 1.82 to 1, and the piston displacement 237.5 cubic inches. Thus the advantages of a long-stroke are added to those of continuous turning effort. The motor operates at moderately high speed and this is accomplished by the use of light reciprocating parts along with well-balanced construction.

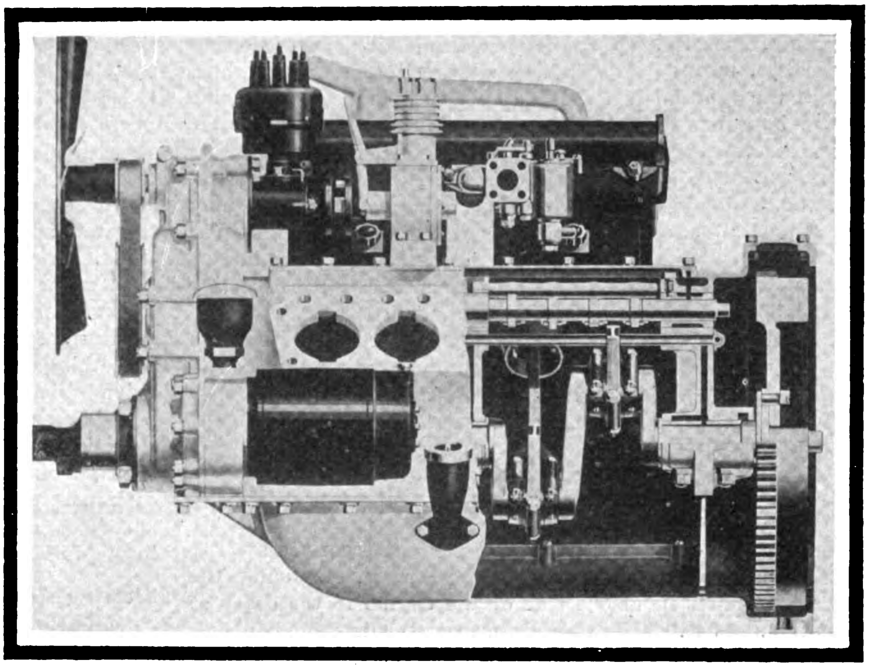
Power Plant Very Short

Compactness is also to be noted, for the power plant unit is really practically the same length overall as the four-cylinder King engine. In fact, for test purposes, one of these eights has been installed in a standard four-cylinder chassis without making any changes save the removing of the four-cylinder power plant. As a result of this compactness and lightness of parts, the engine is said to weigh approximately the same as the four. Of course, they are smaller cylinders, the four-cylinder motor having a bore of 3 15-16 inches.

In the general motor design, the aluminum crankcase is common to both blocks of cylinders, the upper half carrying the crankshaft, and the lower part forming the oil pan. The removal of this pan gives access to the bearings just as in any two-part crankcase design.

Yoke-End Rods Used

The crankshaft is a simple three-bearing type with the throws all in one plane, in fact, it is in the crankshaft that an eight of the V-type has a distinct advantage over a six. By coupling two connecting-rods to each throw bearing, it is possible to use a shaft exactly similar in form to that required for a four. In order to fasten the connecting-rods of each opposing pair of cylinders to the same bearing, one rod has a yoke end, and the other rod is made with a small end which goes between the arms of the yoke. Each of these arms is provided with its cap to go around the bushing. Pins fasten the rod to the bushing so that it oscillates with the rod on the shaft bearing. The small-end connecting rod is free to move on the bushing, its bearing therefore being the outer surface of that portion of the bushing between the arms of the yoke. Both the main bearings and the connecting-rod bearings are babbitt-lined bronze. All have a diameter of 1 11-16 inch with the following lengths: front main, 3 inches; center main, 1 3-4 inch; rear main, 4 inches; connecting-rods, 2 3-4 inches.



Part sectional view of King eight-cylinder motor. The two rear cylinders on the left side have been cut away entirely to show the camshaft in the center of the engine and also the crankshaft and connecting-rods of the corresponding cylinders on the right. The two front cylinders are removed to show the mounting of the ignition distributer, the carbureter, etc., between the cylinder blocks

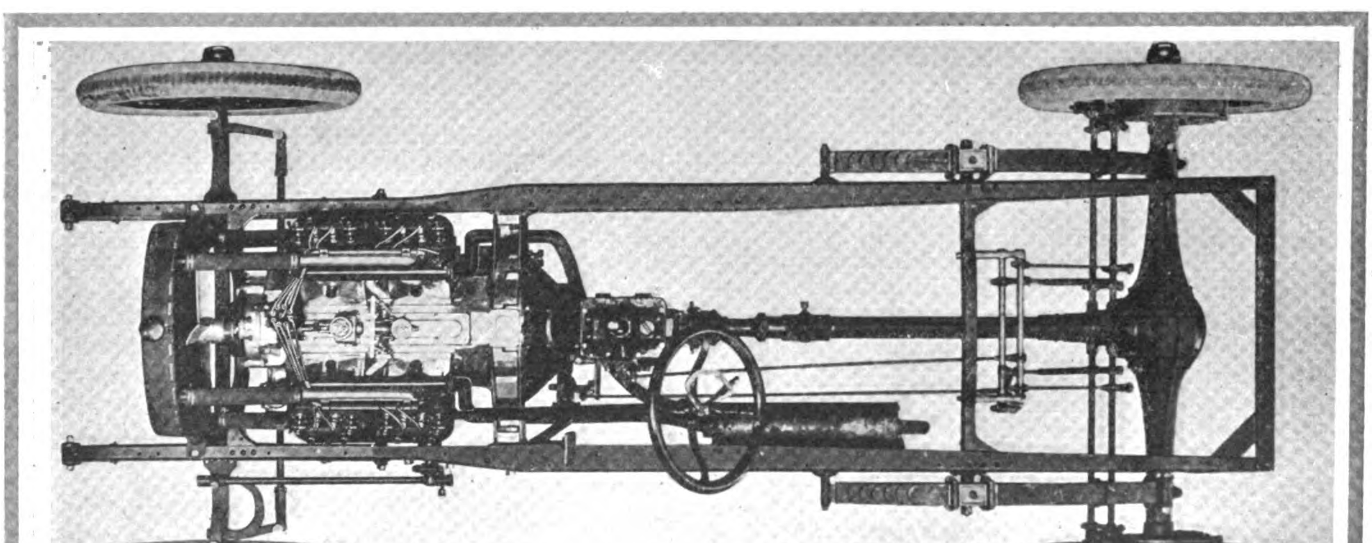
Access to Camshaft

The camshaft is mounted on three bearings vertically above the crankshaft. Its bearings are in the crankcase, and a plate bolting to the top of the crankcase between the two cylinder blocks gives access to the cam assembly. Like the crankshaft, the camshaft is the same type as would be used in a four-cylinder motor, having eight cams, each of which operates two opposite inlet valves or two exhausts. Pivoted to the crankcase are small rocker arms which go between the valve tappets and the cams. These are necessary so that the valve lift will be straight upward on the valves, the rockers through their small rollers bearing against the cams, taking the side thrust. The front camshaft bearing is phosphor bronze, measuring 1 inch diameter by 3 3-4 inches length. The center and rear bearings are of babbitt and their dimensions are respectively 1 11-16 by 1 3-4 inch, and 1 by 2 1-2 inches.

Valves are conventional bevel-seated types 1 3-8 inches diameter and 15-32 inch lift. With a motor of this kind where each cam does double duty in operating two valves, there is only one practicable timing, in which the inlets open at top dead center and close 45 degrees past bottom dead center, and the exhausts open 45 degrees before bottom center and close at top center. Intake and exhaust valves are interchangeable.

The camshaft is driven by a Link-Belt silent chain which in addition to working over sprockets on camshaft and crankshaft is carried over a small third sprocket to the right of the two main ones. This serves two purposes; first for driving the pressure oil pump, and second to give a means of adjusting the chain. The latter is accomplished by moving the small sprocket slightly to the right so as to increase the distance from the centers of this sprocket and the two main sprockets.

Back of the sprocket driving the camshaft and oil pump, the crankshaft carries another sprocket over which another chain runs to the left to the generator sprocket. The position



Plan of King eight-cylinder chassis, showing mounting of motor and gearbox, inclosed driveshaft, characteristic cantilever rear springs, rear axle, etc. Note duplicate water connections for cooling the two cylinder blocks. The thermo-syphon method is employed of the generator may also be shifted slightly to take care of wear on this chain. On the camshaft and back of its sprocket there is a spiral gear meshing with a smaller gear which drives the ignition distributer shaft that is directly in line above both camshaft and crankshaft. As the distributer proper is vertical, a worm-and-gear mechanism transmits the horizontal drive into vertical. On the end of the horizontal part of the distributer driveshaft is a dog clutch which may be shifted to engage the single-cylinder tire pump on the top plate of the crankcase between the cylinder blocks. Chains and distributer driving gears are all completely housed by an aluminum plate, and they run in oil.

The carbureter is a specially-designed type having two openings, one connecting directly to the straight horizontal intake tube running to the single opening in each cylinder block. Distribution to the several ports is effected within the casting. The carbureter is fitted with a hot-air pipe, and gets its fuel from a tank carried at the rear of the chassis.

The Firing Order

The ignition distributer takes its current from the storage battery, and has hand and automatic control. In firing, the order alternates from one side of the engine to the other so that impulses will balance and an even turning effort result. Calling the first cylinder on the right No. 1, the second on the right No. 2, and so on, and considering the first on the left as No. 5, the firing order is 1, 8, 3, 6, 4, 5, 2, 7.

The motor is lubricated by pressure feed by means of the chain-driven pump which is of the gear type, and lifts oil from the oil base up through a horizontal supply tube lying along the inside of the crankcase, this delivering oil directly to each of the three main crankshaft bearings, from which it is forced through the holes drilled in the crankarms to the connecting-rod bearings. The center main bearing in this way delivers oil to rod bearings Nos. 2 and 3, while the front cares for No. 1 and the rear for No. 4. The oil thrown off by the crank bearings lubricates the cylinders and the camshaft bearings.

Thermo-syphon cooling is used. There are separate outlets and inlets from each cylinder block to the cellular radiator, which is aided in its work by a 16-inch fan. Free circulation is furthered by the 5-8-inch water space in the jaekets. The absence of water pumps is a factor in securing simplicity.

The electric cranking and lighting system, of Ward-Leonard make, is a 6-volt two-unit type with the generator attached to the outer left side of the crankcase and driven at twice crankshaft speed by a silent chain. The cranking unit is on the right rear side of the crankcase next to the flywheel to which it connects in the usual way. There is no intermediate gear, the starter pinion meshing directly with the flywheel teeth. The ratio is 10.5 to 1; that is, the electric motor runs at ten and one-half times the velocity of the crankshaft.

In connection with the system a Willard 80 ampere-hour battery is placed under the right front seat, where it is readily accessible. The system operates on 6 volts.

Nothing new to King design appears in the chassis and drive system. Clutch and gearset are in unit with the motor, a bell-housing bolting to the flywheel housing by flange construction inclosing the mechanism compactly. The clutch, a multiple-disk type running in oil, has bronze plates against cork-inserted steel ones. The gearset is a conventional three-speed, selective type with its shafts carried on roller bearings. It has center control levers.

Floating Axle Details

The drive shaft is fitted with a universal at its front end, and back of it enters a compactly-designed torsion tube which is in unit with the pressed steel housing of the floating axle. This has a large cover plate at the rear to give access to the differential and driving gears. Ball bearings are used throughout the axle.

The braking system is of the usual external contracting service and internal expanding emergency type acting on rear drums, which are 14 inches in diameter by 2 inches wide. The brake operating rods are a part of the axle unit.

In this new car, the cantilever form of rear springs is still adhered to, the King company having used them since it brought out its first car some years ago. They have a trunnion mounting to the frame rail a little forward of the center of length, shackle at the rear to the axle housing, and at the front to the frame.

The frame is a bottle-neck design which is light and strong. Three cross-members in addition to the bracing given by the motor make it rigid. There is a slight kick-up at the rear to clear the axle.

Alma Truck Used as a Gospel Wagon

Nowadays when the wise promoters of motor trucks as a commercial necessity have decided that they have been put to every kind of service imaginable, it is interesting to discover a new use for them. It has remained for one of the leading Evangelistic church organizations of the United States to press them into their service as "gospel wagons." Recently the Alma Motor Truck Co., Alma, Mich. was called upon to construct a special type of body on one of its standard truck chassis which would serve both as a home for the Evangelists and a pulpit as well.

The truck was recently delivered and is now doing service throughout the South. Mr. Diehl, driver of the unique truck will travel all through Florida, Tennessee, Kentucky, Alabama and neighboring states spreading the gospel.

Five-Passenger Reo Six for $1,385

Cylinders Cast in Threes and Cantilever Springs, Features —Price of Four Reduced to $1,050—Coupé Added to Line

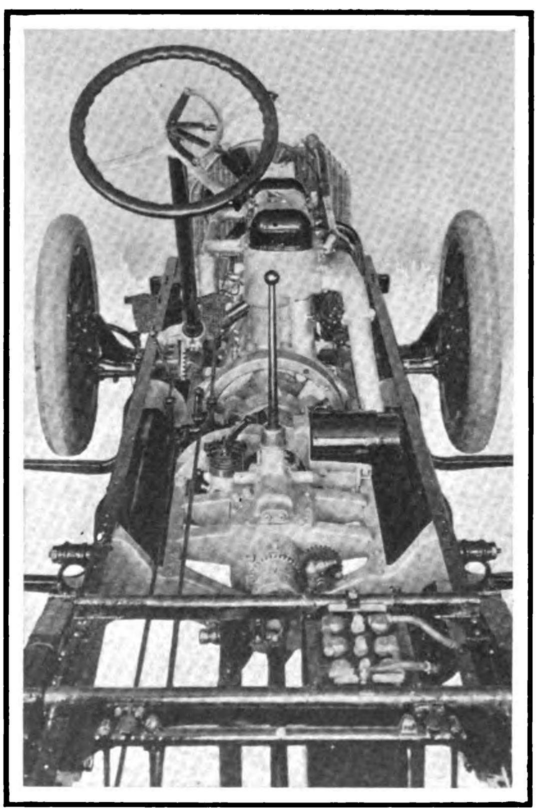
A SIX-CYLINDER, five-passenger car with a wheelbase of 122 inches and selling at $1,385 will be made for 1915, by the Reo Motor Car Co., Lansing, Mich. In the main it follows the design of the Reo four, the two main points of difference being the complete inclosure of the valves and the adoption of cantilever rear springs.

A substantial price reduction has been made on the four and a coupé has been added to the line which formerly consisted of two-passenger and five-passenger open cars. This year the price of both touring car and roadster was $1,175, but next year the touring car will sell for $1,050 and the runabout for $1,000. The coupé sells for $1,575.

Cylinders in Threes

In the six, cylinders are cast in threes. The bore and stroke are 3.563 by 5.125 which gives a piston displacement of 306.4 cubic inches and a stroke bore ratio of 1.43 which places this new Reo distinctly in the long-stroke class as distinguished from the new four which has cylinders 4.125 by 4.5 giving a ratio of 1.09. The S. A. E. rating is 30.4.

The chassis is divided into three units, the motor, gearset and rear axle being separate. The motor and gearset, following standard Reo construction, are mounted on a sub-frame. The electric equipment is furnished by the Remy company. The combined ignition and lighting generator is situated on the right side of the motor, while the starting motor is between the clutch and gearset. The wheelbase is 122 inches and the tires are 34 by 4. The tread is standard, being 56 inches.



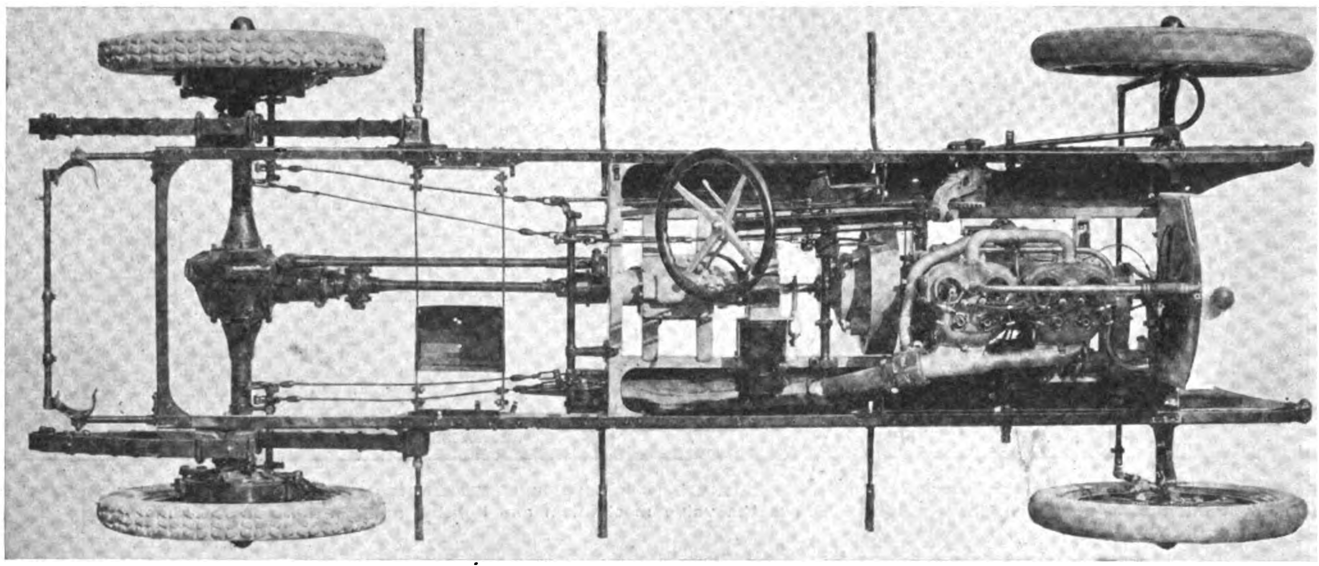
Reo six chassis, looking forward, showing the mounting of the control levers, the position of the starting motor to the right of the gearcase and the suspension of the storage battery from the frame

The six motor has its cylinders cast in threes, and is supported at four points. These dimensions give an S. A. E. rating of 30.4 horsepower. It follows Reo construction in that the intake valves are situated in the head and the exhausts are on the right. This motor differs from its smaller brother, however, in that the rocker mechanism on the cylinder tops is inclosed by sheet metal covers held in place by two coil tension springs. Cover plates also inclose the push rods and valve stems. The crankshaft is carried on four main bearings and the camshaft on three. Both are one-piece drop-forgings. The camshaft is driven directly from the crankshaft by helical gearing. Cooling is provided for by a vertical tube radiator through which water is circulated by a centrifugal pump situated on the left side of the motor. It is driven from the crankshaft by a special pair of gears. The flow of air through the radiator is aided by a six-bladed belt-driven fan. Motor lubrication is by means of a circulating-splash system in which a plunger pump is used.

Mixture is supplied through a Johnson carbureter which is placed very low, a long water-jacketed manifold connecting it with the motor. Fuel feed is by gravity. Additional heat is supplied by means of a hot air connection on the exhaust pipe.

Remy Electrical Equipment

The electrical equipment consists of a 6-volt Remy two-unit system and a Willard 100-ampere-



Bird's-eye view of Reo six chassis showing the arrangement of the different members. Motor and gearset are suspended on the sub-frame from four points. The axis of the armature shaft is at right angles to the crankshaft and drives the motor through a worm gear. Since the driving gearing is behind the clutch the latter must be engaged when the motor is to be started. Note the cantilever rear spring suspension and the floating rear axle

hour storage battery. A single instrument combines the ignition and lighting functions. It is located on the right side of the motor and is driven through a leather coupling. The starting motor location is unusual in that it is placed just in front of the gearbox and to the right of it. It drives the engine through worm gearing and when cranking is to be done the clutch must be engaged, because the starter drive is behind the clutch.

The clutch is a dry-plate type and is situated in a housing bolted to the flywheel. The friction surface is steel against asbestos.

Three speeds are afforded by the gearset which is suspended from the sub-frame by four arms. The shifting lever is mounted directly on the top of the gearcase cover, which also contains the shifting rods. The gear lever is carried in a ball and socket joint. Hyatt roller bearings are employed in the mounting of both main and countershafts.

From the gearset the power is transmitted to the rear axle through a drive shaft fitted with two universals. A torque rod which is attached to a cross member of the main frame relieves the springs from the torque reaction of driving the wheels. No radius rods, however, are fitted, the cantilever springs taking the driving thrust. The cantilever springs are pivoted to the frame at their centers and are shackled at the front ends.

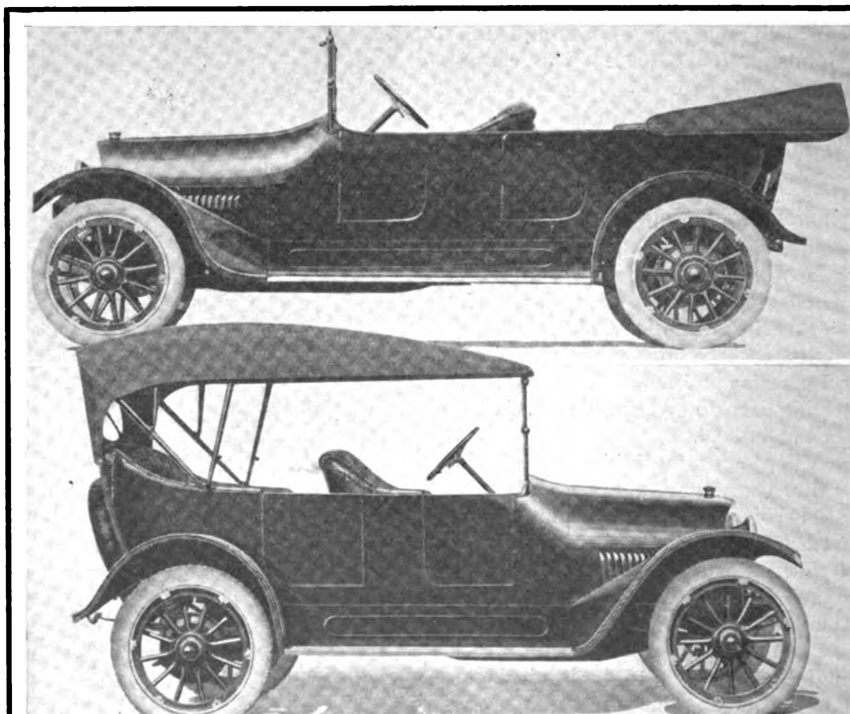
Floating Axle

The axle is a floating design, fitted with Timken bearings and notable because of the use of a spiral bevel gear and pinion to insure silence of operation. The ratio is 3.7 to 1. The brakes operate on the rear wheel drums which are 14 by 2.25 inches. The tires are 34 by 4 and are fitted with demountable rims which are mounted on wooden wheels. Front springs are semi-elliptic.

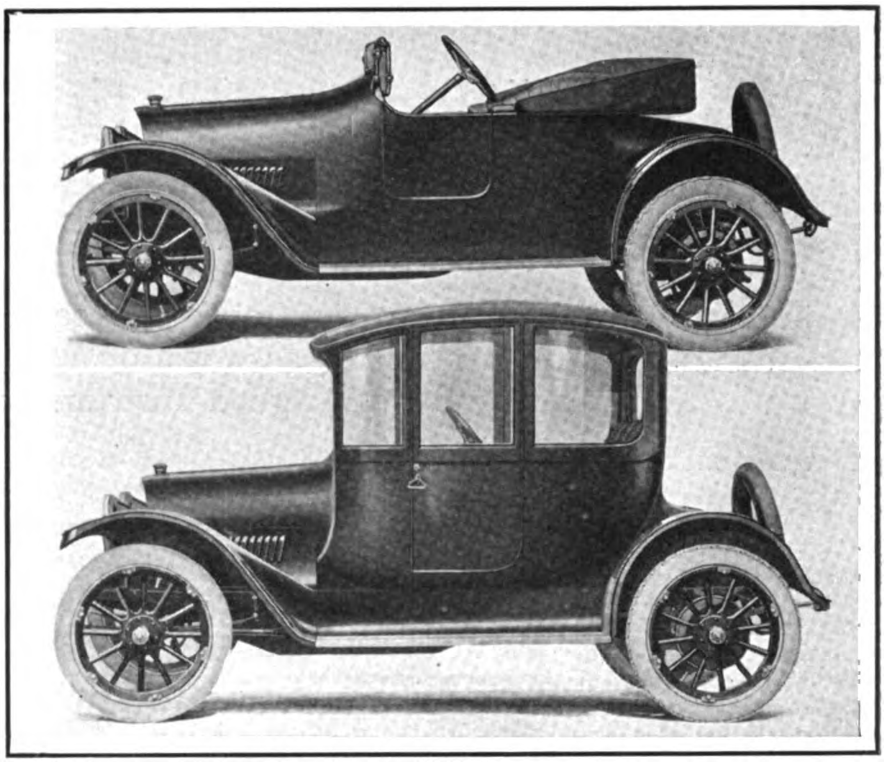
Left drive and center control have been adopted. The steering gear is a rack and pinion design. The emergency brake is controlled by the right pedal which usually actuates the service brake. This pedal is provided with a ratchet to hold it locked. The left pedal operates both clutch and service brake, the outward movement of the pedal first disengages the clutch and then applies the brake. This pedal is also provided with a ratchet lock.

The equipment includes a Stewart-Warner speedometer, one-man top with quick-detachable curtains, rain-vision, ventilating windshield, tools, extra rim, tire carriers, etc.

Smooth curves and clean running boards characterize the body design of the Reo six. As in this year's four, the top of the radiator points outward in a way that makes the car



Above—New Reo six. Below—Four-cylinder Reo with top up



Upper—Reo four runabout. Lower—Reo coupé

easily distinguishable. A feature is noted in the shaping of the front fenders. The inside of the fender is a straight line running to the frame, while the outside is curved to follow the wheel. This not only gives a pleasing effect, but also affords maximum protection against the spattering of mud. The smoothness of the body lines is accentuated by carrying the sides of the body down over the frame side members.

An increase of .125 inch in the bore is the principal difference in the new four. The cylinders now measure 4.125 by 4.5 inches, the S. A. E. rating being 27.2 horsepower. As in the case of the six, motor and gearset are mounted on a sub-frame, each being suspended from four points.

The cylinders are cast in pairs, the intake valves being mounted in the center of the head and the exhaust valves at the right side. Both crankshaft and camshaft are supported on three bearings, the camshaft being driven by helical gearing. Cooling is maintained by a tubular radiator assisted by a centrifugal pump and a six-bladed fan. Lubrication is by means of a circulating splash system in which a plunger pump is employed.

The electrical equipment is the same as that used on the six, while the carbureter is a Holley. The intake manifold is not water jacketed but a hot air pipe is fitted. Fuel feed is by gravity from a 16-gallon tank under the front seat.

The clutch and gearset and the mounting of the electrical units are the same as on the larger car. Drive is transmitted to the rear axle through two universals, and a torque tube is fitted. The gear ratio is 4 to 1. The rear axle is a semi-floating design on which are mounted three-quarter elliptic springs. The brakes eare 14 by 2 inches, both sets acting on the rear wheel drums. Timken and Hyatt roller bearings are used in the rear axle and in the front axle Timken bearings are used exclusively.

The equipment includes a Stewart-Warner speedometer, three-bow extension top with quick-detachable curtains, rain-vision, ventilating windshield, tools, extra rim, tire carriers, etc.

The body design of the four resembles that of the six and follows Reo design of this year except that the shape of the rear door is fuller, instead of the lower rear corner being cut off to make room for the fender.

Four Body Like Six

The body on the new runabout is the same as that of this year, but with slight refinements which add to its appearance. The coupé is a design in which the details have been thoroughly worked out. The upholstery is cloth and the windows are frameless. A rain-vision glass front allows the driver to see the road properly even in rainy weather. There is a space at the rear for tools and tubes and back of this is the tire carrier and spare rim.

Vanadium Discovered Near Lake Superior

DETROIT, MICH., Dec. 7—Vanadium has been discovered by J. N. Thompson, a mineralogist, near the shore of Lake Superior, about 35 miles northwest of L'Anse, it is reported.

The mineralogist has been prospecting for a number of Chicago iron interests and made the discovery of a vein of vanadium several weeks ago. The matter was kept secret, but arrangements were made at once for the construction of a shaft and crew of men was put to work to further investigate the grounds. The vein is reported to be 24 inches thick and runs for a very great distance. In fact it is estimated that the output will be exceptionally large in quantity and value. Although vanadium has been found in five Western States, in only two has it been found worth the while to mine it, but even so, the quantity produced is quite small and practically all of the vanadium used in the United States comes from Europe and most of it from Sweden.

Vacuum-Velocity Ratio Not Constant

The Automobile Engineers' Forum

Carbureter Inventor Cites Simultaneous Readings in Mixing Chamber and Venturi Throat as Basis of a Mathematically Designed Instrument

NEW YORK CITY, Dec. 5—Much discussion has arisen over the principles of operation in the new Browne carbureter recently described in these pages and A. B. Browne, inventor of this carbureter, answers many of these criticisms in the following communication and shows wherein the carbureting conditions in his design differ from those in other types:

BRANFORD, CONN.—Editor THE AUTOMOBILE:—In discussing the principles used in the Browne carbureter we must first recognize that in the ordinary auxiliary-valve carbureter, the force acting on the valve is not the same as the force acting on the mouth of the fuel jet.

In proof of this, turn a stream of compressed air through the primary inlet of any carbureter. Fuel will be inspirated by the velocity of the air passing the fuel jet, although the pressure in the carbureter is above, rather than below, that of the atmosphere. This is the well-known principle of the atomizer. Because the pressure within the carbureter is above atmospheric, the common auxiliary valve is pressed tightly against its seat.

If now, suction is applied, instead of pressure, and the primary inlet closed, fuel will again be inspirated, this time by the static vacuum, for because the inlet is closed, there will, in this case, be no air passing the fuel nozzle to exert its inspirating effect. In this case the auxiliary valve opens.

Velocity and Vacuum Actuate Fuel Flow

By these two experiments we have proved that the fuel flow is actuated by velocity and vacuum while the auxiliary valve operates by vacuum alone.

It is next necessary to prove that although the vacuum induces the velocity, that:

A—The combined forces of vacuum and velocity are greater than either acting alone.

B—That the relationship between the two forces is not constant.

In proof of A, I cite actual simultaneous readings of injecting force in inches of water.

On the auxiliary valve in the mixing chamber		On the fuel at the throat of the venturi	
0.5	inch	1.31	inch
0.875	inch	1.93	inch
1.0625	inch	2.875	inches
2.5	inches	5.5	inches

B—The foregoing readings were taken during a period of no barometric or temperature change and hence the relationship remained practically constant.

Suppose, however, as an exaggerated illustration, that in one case the velocity over the fuel jet was that of entering air while in the second case it was that of mercury vapor. The vacuum in both cases could be maintained the same but the velocity effect of the heavier mercury vapor would be very different from that of the lighter air.

This is clear, mathematically, when we remember that density is a factor of head and that head is proportional to the square of the velocity and not velocity direct.

Constantly Varying Factors

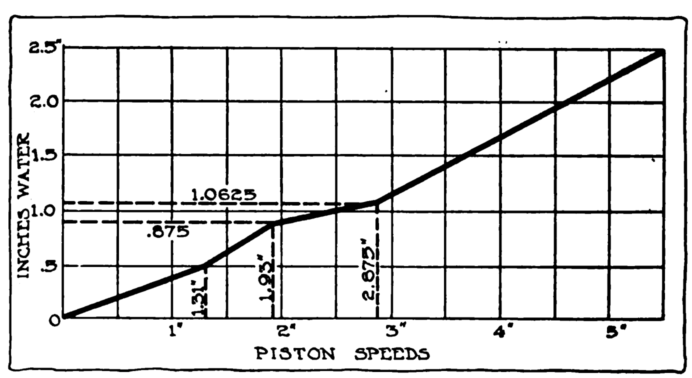
Summarized then, we must admit that there is no constant kinetic characteristic of air, so far as carburetion is concerned. Temperature, pressure and consequently volume, are constantly changing and hence the relationship between the forces acting on the fuel nozzle and upon the auxiliary valve are constantly varying. The best we can do is to eliminate this variation instrumentally, by causing the same forces, whatever they are, to act on both fuel and air supply. This the Browne does and, repeating our first experiment as above, we find the flow of compressed air actually opens the auxiliary valve instead of forcing it shut as in the ordinary carbureter.

Velocity Determines Curve of Inlet Areas

Having accomplished elimination of variables it becomes an easy matter of design to so proportion the total air inlet area as to maintain constancy of composition. Both the primary and auxiliary inlets must be considered as a unit, but in the Browne, because of greater mechanical convenience, the total area is properly modified by varying the auxiliary inlet only, and inasmuch as the varying degrees of vacuum are fixed, velocity alone enters into the determination of the curve of inlet areas.

Because the areas corresponding to given quantities of air can be and are so accurately determined, it becomes necessary to use a spring accurately calibrated for each instrument, precisely as the spring of a spring balance is calibrated. This is done by passing compressed air through the primary inlet at velocities determined by a venturi meter.

This accuracy would be unobtainable with differing air densities if the disk-type valve were used. The inertia, or the wind, of the incoming air at different densities would change the position of such a valve relative to the curve of

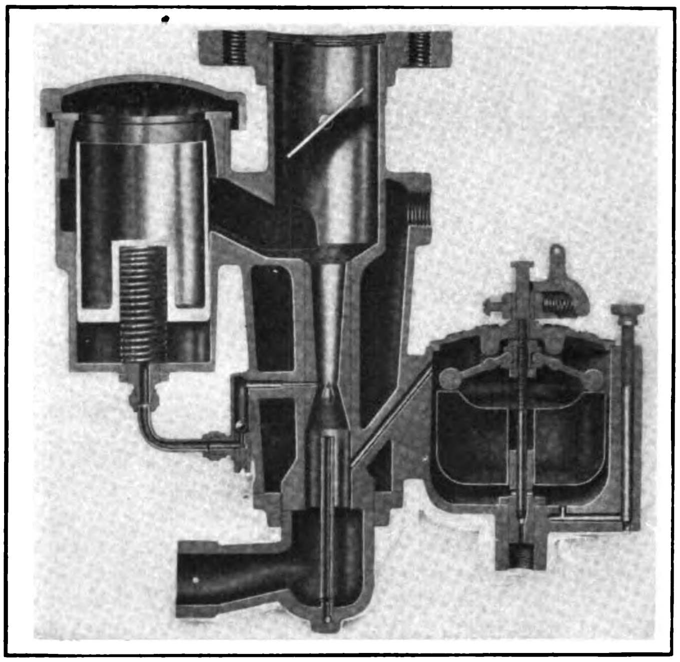


Curve illustrating the theory that the combined forces of vacuum and velocity in a carbureter are greater than either acting alone, as deduced from a test comprising actual simultaneous readings of injecting force in inches of water on the auxiliary valve in the mixing chamber and on the fuel at the throat of the venturi admission areas and hence our valve is made cup shaped, presenting practically no surface to the inrushing air. In effect this is an adaptation of the bug used by Western miners where a candle inserted through the side of an open ended can, fails to be blown out, even with a stiff gale blowing directly into the open mouth of the can.

Keeping Out Dirt and Preventing Air Leaks

One more point is worthy of consideration. The air current passing from the auxiliary opening in the mixing chamber traverses a path at an approximate right angle to the vertical axis of the valve. The velocity is here again utilized to exert a suction where the valve enters its cylinder, in this way preventing dirt from entering and counteracting possible air leakage past the valve. The effectiveness of this is proven by the fact that I have driven one of these carbureters 16,000 miles, with no cover on the auxiliary opening, and the valve today is nearly as bright as when first put in, and shows not the slightest sign of wear.

Our instrument is the embodiment of a conception of natural law and frankly I have spent the greater part of 3 years attempting to prove some weakness in this conception but absolutely without success. Deviations always led us directly back to the original basis and this given, design was a simple matter.—ARTHUR B. BROWNE, designer of the Browne carbureter.



Section through Browne carbureter, which has vacuum air control

Court Decisions—Motorist Recovers Damages

By George F. Kaiser

THAT a purchaser of a motor car on his rescission of the purchase for false representations is entitled to recover back the entire amount he paid for the car, although part of that amount was given as a commission to agents, was recently decided by the highest court in Texas.

In 1913 a motorist, desiring to get a better and more up-to-date car than the one he owned, applied to a garage owner in the town where he lived and told him that he was impressed with a certain car and, although the latter was the agent for another car, he undertook to get the agency for the car desired.

The garage man took the matter up with the agents of the factory and was told by them that if a commission was made they would divide it. He succeeded in selling a new car to the motorist and allowed him $550 for the old car in part payment. The new car was represented to be a four-cylinder, four-passenger, 30 horsepower car, first class in all respects, and a good hill climber and able to go from Dallas to Celeste on high gear. The car turned out to be defective and not as represented. The purchaser therefore attempted to rescind the contract and get back the money which had been paid by him.

The Court held that he was entitled to do this notwithstanding the fact that $200 commission had been divided between the garage man and the agents.—*Halff vs. Jones*, 169 *S. W.*, 906.

Must Stop After Accident

California Court of Appeals decides that motorists must stop and give their addresses whenever an accident occurs.

California has a statute somewhat similar to the statute in New York and other states, which provides that whenever an automobile strikes a person or collides with another vehicle, the driver shall stop the automobile, attempt to give assistance to the other vehicle and furnish the number of the offending car, together with the name and address of the driver and owner and the names of the passengers.

While a car was being operated by a motorist in California, it collided with another automobile and the chauffeur of the first car did not stop, nor give his name, number, etc. He was convicted of violation of the above statute and it was held that his argument that such a collision might occur under such circumstances as to render him criminally liable and that therefore the statute was unconstitutional could not avail him, as it was the right of the Legislature of the state to attach any restrictions or conditions to the operation of motor car vehicles on the highways that it thought necessary.—*People vs. Diller*, 142 *Pacific* (*California*), 797.

Chauffeur Acting for Owner

When a person seeks damages from an automobile owner whose car is driven by a chauffeur at the time of a collision, he must set up that the chauffeur is acting for the owner at the time of the accident.

A person was struck and injured by an automobile which was driven by the owner's chauffeur and subsequently he brought suit against the owner for damages for his injuries. The Court held that the action against the motorist could not be sustained because although the chauffeur was named, the injured party did not allege that at the time of the accident the chauffeur was the motorist's servant, or that the chauffeur was acting for the owner at that time.—*Ruban vs. Bierman*, 149 *N. Y. Sup.* (*New York*), 483.

NEWCASTLE, IND., Dec. 7—The fact that an automobile dealer has machines on the freight track, with a sight draft attached to a bill of lading does not in any way impair his financial credit. This point was brought out in receivership proceedings at the Henry Circuit Court here. Charles W. Mouch, president of the Farmers' National Bank of this city, and a minority stockholder in the Rose City Auto Co., filed a petition for the appointment of a receiver for this company. Judge Fred C. Gause, in an oral decision handed down, refused to appoint a receiver and stated that the corporation was entirely solvent, the evidence showing a healthy condition of affairs.

The Improvement of Spring Suspension—II

By M. C. K.

(Continued from issue of November 26)

The basic idea: To express the requirements in the springing of motor vehicles in definite mechanical terms; to do this by ascertaining and describing the movements and actions occurring under different conditions and comparing them with those desired; to ignore refinements until the fundamentals seem clear—in brief, to make the subject accessible.

IN trying to determine the movements to which a vehicle is subject by reason of inequalities of the road surface, with a view to ascertaining the best means for getting only such movements as are consistent with security and comfort, it is found necessary to examine first (1) the movements made by a vehicle entirely devoid of spring suspension elements of any description, then (2) those of a vehicle fitted only with ordinary vehicle springs, thereafter (3) those of a vehicle fitted with springs and elastic tires and finally (4) those of vehicles equipped with springs, elastic tires and representative selections among the auxiliary devices which have been developed specially for the requirements of speedy motor vehicles. In this instalment only a part of the foundation for subsequent comparisons can be laid, consisting in an examination of the action which must follow when an entirely unelastic vehicle strikes an obstacle of the simplest shape on a level road. As entirely unelastic vehicles do not exist in reality, the result of this preliminary examination cannot be anything more than a contribution to the clearing up of the ideas which subsequently enter in the more practical phases of the large subject. It should, however, dispose of the rather widespread impression, which is frequently countenanced unthinkingly even by those who are deeply versed in other aspects of spring suspension matters, to the effect that the jouncing and the shocks of vehicles, which are both sources of danger and discomfort, are also due to the same causes and can be obviated by the same means.

In each of the four classes not only the movements caused by simple road obstacles but also those caused by depressions in the road surface and by successions of humps and of hollows at various distances apart, as well as of humps and hollows in combination, must eventually be considered with reference to different vehicle speeds and road gradients, but this will be postponed until the more fundamental comparisons shall have been disposed of; whereafter the reasoning becomes easier.

(1) Movements of Vehicle Devoid of Springs and Other Elastic Elements

The suppositions are: A vehicle weighing 3,000 pounds, of which the rear wheels and axle with the load thereon represent 2,000 pounds and the front wheels and axle with load make up the remaining 1,000 pounds; the wheels are 40 inches in diameter; a speed of this vehicle of 50 feet per second, which corresponds to about 35 miles per hour; a level road with an entirely unyielding transverse ridge of triangular section, 3 inches high with a base of 6 inches.

What happens to an absolutely unelastic vehicle when it strikes a road obstacle is not unlike that which happens to the running-gear, with hard tires on the wheels, of a motor truck for example, if the action of the running-gear is considered separately from that of the springs and the load supported on it; that is, the forces are similar, but the resulting movements are made to vary through the reactions of the load and the springs upon the running-gear; also, the running-gear is in practice never absolutely unelastic. The similarity nevertheless becomes of interest in the subsequent development of the subject and especially for a comparison of the relative merits of two spring suspensions, one composed of ordinary vehicle springs eased by means of elastic tires and the other of more specific spring arrangements in connection with tires of scarcely any elasticity.

The laws of gravitation must be constantly consulted to determine the movements of the vehicles in all four classes. For convenience there is therefore given herewith in Fig. 2, a scale of the time t in fractions of a second which it takes for a weight to drop back to the level of a road from different heights h. It gives the time for heights from 1 inch to 12 inches, and thereafter for even feet from 2 to 16. In figuring this scale and in all other cases, the factor of acceleration by gravity, g, has been taken as 32 instead of 32.16 or 32.20, this giving $t = 1/4\sqrt{h}$ from the basic formula, $h = 1/2gt^2$.

Gravitation Data

Acceleration by gravity $= g = 32.16$ feet per second
Time in seconds $= t$
Velocity acquired $= v = gt$
Height of fall or rise $= h = \frac{1}{2}gt^2$
Initial velocity $= c$
Height of rise against gravity $= h = \dfrac{c^2}{2g}$
With g taken as 32, $t = \frac{1}{4}\sqrt{h}$

SCALE OF $t = \frac{1}{4}\sqrt{h}$ FOR DIFFERENT VALUES OF h

h	t	h	t
1 inch	0.072	3 feet	0.434
2 inches	0.102	4 feet	0.500
3 inches	0.125	5 feet	0.559
4 inches	0.145	6 feet	0.612
5 inches	0.161	7 feet	0.661
6 inches	0.177	8 feet	0.707
7 inches	0.191	9 feet	0.750
8 inches	0.204	10 feet	0.791
9 inches	0.216	11 feet	0.829
10 inches	0.228	12 feet	0.866
11 inches	0.239	13 feet	0.901
1 foot	0.250	14 feet	0.935
2 feet	0.353	15 feet	0.968
		16 feet	1.000

Fig. 2—Reference formulas and figures related to the movements of vehicles in rising from or returning to the road level after a shock

Beginning with front wheel action, to climb the ridge means to raise the weight of 1,000 pounds to the height of 3 inches in the time elapsing from the moment when the wheels strike the ridge till they are squarely on top of it. For simplicity, the two wheels may hereafter be referred to as one.

By reference to Fig. 3 it is seen that the distance covered by the vehicle in this time is b and that this is one side of a right-angled triangle; hence $b = \sqrt{20^2 - 17^2} = \sqrt{111} = 10.53$ inches.

Moving at the rate of 50 feet per second, and considering that retardation due to the shock received by striking the ridge is negligible, the vehicle covers 10.53 inches in 0.01755 second and imparts an upward movement of 3 inches to the front portion of the vehicle.

At this point in the reasoning the current opinions part, and for the sake of clearness the view of the action most commonly entertained must be presented first. According to it, it is assumed that the upward movement at high velocity results in a bound and that the extent of the bound—the vertical movement being so far the only component considered—depends on the velocity. The height of the bound is in this manner easily figured:

It is determined from the formula, $h = \frac{c^2}{2g}$, in which c is the initial speed in a vertical direction imparted to an object and h the total height reached by the object with gravitation constantly acting against its rise. In the present case $c = 3$ inches in 0.01755 second, which is the same as 171 inches or 14.25 feet in 1 second. The formula thus gives:

$$h = \frac{14.25^2}{64} = \frac{203.0625}{64} = 3.18 \text{ feet.}$$

The front portion of the vehicle is thus thrown up in the air to a height of 3.18 feet, if it may be assumed that its connection with the rear portion does not hinder or assist the movement.

The time occupied in going up is the same as for coming down again, as the velocity decreases in going up exactly at the same rate as it increases in coming down. The drop from a height of 3.18 feet, (according to: $t = 1/4 \sqrt{h}$ or by interpolation from scale in Fig. 2) takes 0.445 second, and the total time of the bound is therefore 2×0.445 sec. $=$ 0.890 sec. This gives the width of the leap, for in 0.890 second the whole vehicle advances—still on the supposition that its momentum is not appreciably reduced by the impact—at the rate of 50 feet per second, consequently a distance of $50 \times 0.890 = 44.5$ feet, and the movement made is therefore a leap 44.5 feet long and 3.18 feet high, describing a parabola.

Before the front portion has finished this leap, the rear wheels strike the ridge, and this causes the rear portion to make a similar leap, so that the whole vehicle is in the air for a distance of 44.5 feet minus the length of the wheelbase.

Misapplied Reasoning

These figures seem extraordinary, but it is remembered that racing cars, after striking a *caniveau*, have sometimes made leaps described as even more wonderful, and some explanation is perhaps found in the assumption of completely unelastic wheels and vehicle structure acting against an entirely unyielding obstacle, it being remembered that in any sort of practice where no springs are used, as for artillery, for sulkies or in the Russian telega, large forces are always absorbed, in the case of a shock, in deformations and heat generation, while the road obstacle is also more or less crushed by the impact, so that the forces remaining to cause a great bound with these vehicles are considerably cut down. In the discrepancy between theory and practice an explanation has thus been found for the observed fact that unsprung vehicles after all do not make such leaps as described. But there is little comfort in this explanation, because only the velocities and not the masses have been considered in figuring out the trajectory of the vehicle after striking, and it follows from this that the leaps made in practice should equal those declared by theory with only an extra allowance in the matter of the severity of the conditions. For example, a hard obstacle, such as a scantling or a frozen ridge or a railway track 5 inches high, should under that explanation have a similar effect on the trajectory as a theoretical hump 3 inches high.

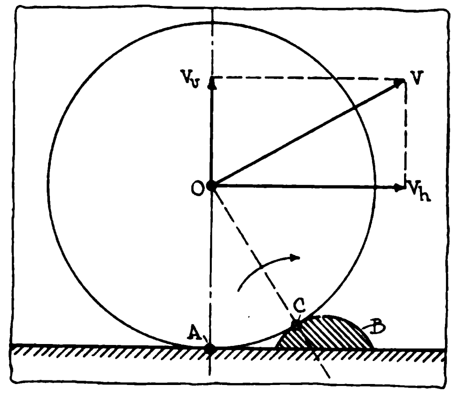


Fig. 4—Dr. Bobeth's illustration

Even Specialists Confused

That the theory which would determine the bouncing of a vehicle from the velocities employed and the height of the obstacle encountered is not purely a popular fallacy or set up merely as a man of straw to be knocked down, is evidenced in one instance. Dwelling on the severity of the vertical component of a road shock, Doctor-engineer Erich Bobeth, whose treatise on *Die Leistungsverluste und die Abfederung von Kraftfahrzeugen* (The Efficiency Losses and the Spring Suspension of Motor Vehicles), 1913, constitutes the most recent exposition of spring suspension requirements and is based on many elaborate tests, has the following to say (page 70 of the work mentioned): "If in accordance with Fig. 37 [reproduced as Fig. 4 in this text] it is assumed that a wheel moves with uniform horizontal velocity v_h and, when reaching the point A, meets the obstacle B, it is compelled to leap over this obstacle. At the moment of striking, the wheel must execute a turning movement around the point C of the obstacle. If the wheel has a perfectly rigid tire and the horizontal speed v_h is to remain constant during the leap, there must at the moment of striking be created a vertical velocity v_v of finite magnitude determined by the parallelogram of forces, while before the striking the vertical velocity was nil. This means however that the acceleration of the wheel in the

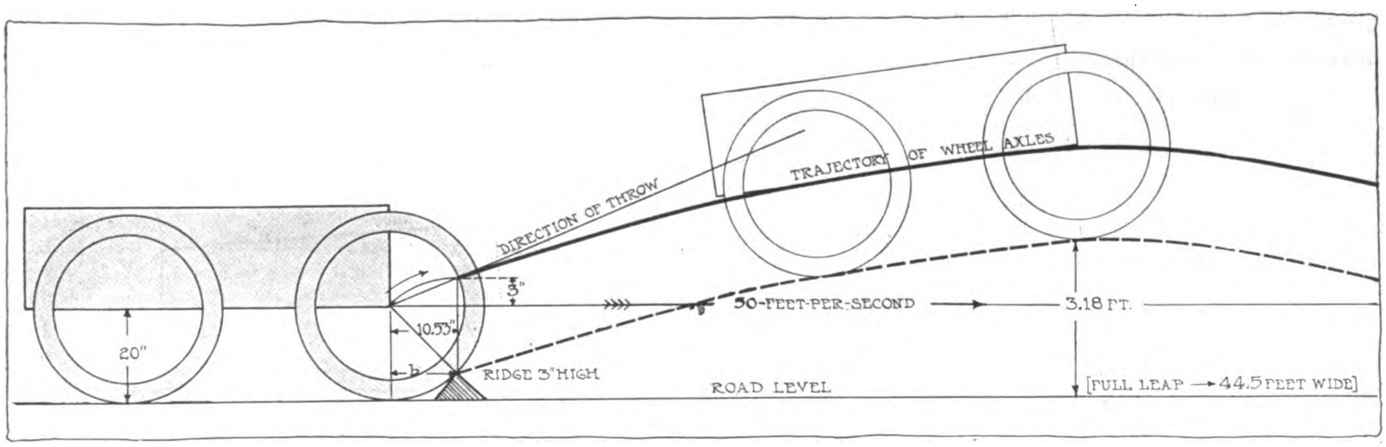

Fig. 3—Representing a graphic translation, based on figures, of a commonly accepted theory, as to what occurs when a fast-moving vehicle without springs or elasticity strikes an obstacle in the road—Not drawn to scale—Curve marked by arrow is part of the wheel axle trajectory, and the lack of continuity where the two portions join suggests the error of the theory

vertical direction must be infinitely great [since O must be multiplied by infinite to produce a finite value]. And an infinitely great acceleration calls for infinite forces, which cannot exist in practice; moreover, destruction of the obstacle or the wheel is first to be looked for.

"It was assumed in this reasoning that the horizontal velocity v_h of the vehicle frame and axle remained unchanged while the wheel passed over the obstacle, and this supposition is generally justified, as the mass of the vehicle is of such magnitude that the retardation at the moment of the shock can be considered as negligible.

"There exist, however, vehicle constructions with which a momentary retardation of the axle with relation to the frame is possible; namely by the use of resilient radius rods [or "driving through the springs"]. The velocity v_h of the axle can then become O at the moment of impact, and this will permit also the vertical velocity v_v to begin at O and to increase gradually, so that excessive vertical acceleration is avoided. It must nevetheless be considered that even with such construction the relative movement of axle and frame is very small and that therefore the mitigating effect of yielding axle struts must be small also.

"A suitable means for holding the vertical acceleration within bounds while the horizontal velocity remains constant [so as to avoid jerky progress] is found in the use of elastic tires. The obstacle impresses itself in some measure in the tire, and the vertical forces, beginning with O, are increased gradually and impart to the axle likewise a gradually increasing vertical velocity."

Dr. Bobeth does not trace the trajectory of an entirely "unsprung" vehicle and perhaps by reason of this omission is not induced to investigate further if the theory of the vertical acceleration due to the shock, which he applies and which is the same that has been applied to construct Fig. 3, is after all properly applicable for any kind of vehicle, with or without spring suspension and tires.

In what else there has been published on the subject similar uncertainty and hesitation prevail on this point, the theoretical conclusions being apparently hard to accept, as they should be, but the hesitation may be ascribed in part to the fact that unsprung vehicles have seldom been seen running at 35 miles per hour against hard obstacles 3 inches high, so that the actual results of such practice are little known. The impact would result in breakage in most cases. Also, a slight reduction of speed, which might escape the estimate in practice, figures out a considerable moderation in results. The writer remembers, however, one instance which might be interpreted either way. A cannon under his command was driven at the highest obtainable horse speed down a steep hill and struck a ridge, higher at one side than at the other, near the foot of the slope, and the leap made was astounding in height, throwing the soldiers a considerable distance, while the unevenness of the shock resulted in twisting the steel plates of the carriage probably 10 degrees.

Reasoning for True Theory

As it is evidently of considerable importance to know what actually does or must take place, with different sorts of impacts, in the case of unsprung vehicles, so as to be better able to appreciate the effects of spring suspension elements, an attempt shall now be made to determine if there is not after all a momentary retardation or other factor of some magnitude at the reception of a shock, which will allow the trajectory described by an unsprung vehicle after striking an obstacle to be drawn more in accordance with natural expectations and practical experience than that which is exemplified in Fig. 3.

Fig. 5 serves to illustrate the reasoning. As the vertical acceleration of the front portion of the vehicle must be produced during the very brief period while the axle B is being deflected from its horizontal course and turned around the point A where the impact takes place and cannot be continued after the point A of the wheelrim has ceased to be actuated, either the whole acceleration is communicated instantaneously or else the possibility exists that it, the acceleration, may be cut short the moment the impulse received becomes sufficiently strong to raise the wheel from contact with the obstacle before B has reached C. An instantaneous acceleration is out of the question, as it implies infinite forces. The inference is therefore that acceleration is received all the way from B to C, provided A remains in contact with the ridge. But it is observed that the tangent of curve BC at C is horizontal, so that, if axle B followed this curve, its upward course would here be finished; also, that any intermediate point of curve BC, such as F, represents a greater rise above the horizontal BD, considered in proportion to the corresponding horizontal progress BG of the vehicle, than the total rise at C to which the horizontal progress b corresponds. The vertical acceleration is therefore stronger nearer the moment of impact and results at one moment or another in raising B above the curve BC; that is, it results in raising A from the ridge, thereby cutting short further acceleration until gravitation takes the wheelrim back into contact with A. As this action operates on the principle of a governor, it is seen that in reality the theory of a violent vertical acceleration and a high leap as the result of an impact of an absolutely unelastic wheeled structure with an entirely unyielding ridge is inconsistent with itself, and that the wheel on the contrary must skim closely—in a series of infinitesimal bounds, it might be said—around the contours of the obstacle till its summit is passed, whereafter the trajectory to the road level depends upon its horizontal velocity. And a corrollary to this conclusion must be that where in practice an unsprung vehicle bounces considerably in passing over a hump or ridge, such action is due to whatever elasticity such a vehicle—or the ridge—possesses despite the absence of springs.

Retardation Not Negligible

It remains a fact that B is raised 3 inches in a certain time and that this time in the present case would be 0.01755 second if no retardation took place. With or without retardation, a force equal to such an acceleration of 1,000 pounds must have been abstracted from the kinetic energy of the vehicle, which is $1/2mv^2 = 1/2 \times \frac{3,000}{32} \times 50^2$. But as it has now been shown that the front axle cannot acquire the vertical velocity mentioned, the wheels on the contrary being compelled to hug the obstacle closely—if elastic elements are absolutely absent—it becomes necessary to conclude that the force of the im-

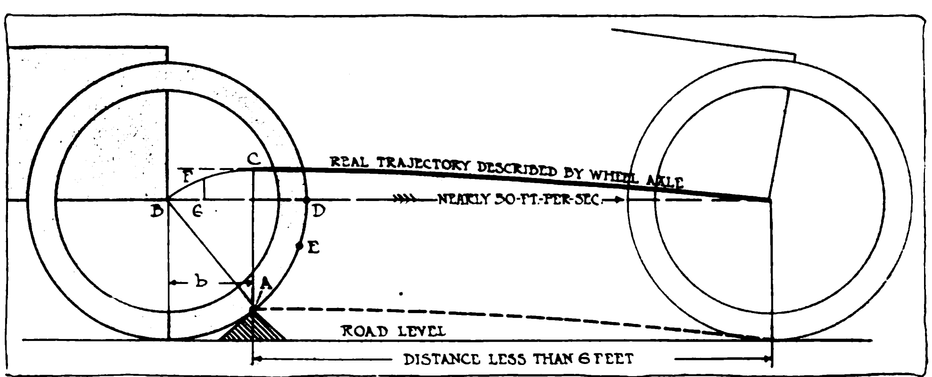

Fig. 5—Representing the movement really made by front wheel of vehicle without springs or elasticity, when it strikes a road obstacle at 35 miles per hour

pact must have been spent mostly in shock of the structure and, furthermore, that this shock means an actual and considerable retardation of the vehicle, resulting in just such a vertical component of the force as makes the wheel rise over the obstacle without surplus velocity for a leap.

The nature of the retardation, resulting, as it does, from converting the rectilinear movement of B into a circular movement for a very brief period is here a difficult element to bring in line with the laws of kinetic energy, whereof later.

As all ideas on the subject are associated with materials and structures having a more or less pronounced capacity for rebounding—in many cases coming into play only when the impact has great force—it is an effort to conceive the situation in the abstract and to realize that whether the front end of the vehicle is light or heavy, provided it is absolutely unresilient, the striking of an obstacle must retard the whole vehicle, which may be very heavy in proportion to the weight of its front portion, sufficiently to prevent this front portion from being thrown into the air more than just enough to clear the obstacle. Some experience with the driving of common unsprung farm wagons at a lively clip over rough ground helps the realization, however.

Transforming Shock Into Movement

It is also plain that if the unyielding obstacle is so shaped and so high as to resist the wheel at D, Fig. 5, it will stop the vehicle completely, and that the component of resistance which tends to arrest the vehicle simply gets gradually smaller below this point. There is thus always retardation. In fact the horizontal component of the force of impact is retardation, usually not so pronounced as to be felt as a shock, and the vertical component is the shock proper, which again is dissolved into destructive shock and motion, the motion being in the case of the unelastic vehicle only that of raising the vehicle over the obstruction and coming down to the road level again, and in all other cases only such additional movement as the constructive conditions permit. The mechanical object of spring suspension is therefore always to transform shock into movement by making movement possible, and to make the movement unobjectionable by extending it as much as possible in the direction of the travel. This becomes especially difficult when shocks are received in quick succession, as the shock forces then, in whatever manner they have been dissolved, accumulate upon a small amount of the forward movement of the vehicle in which they have to be absorbed—that is, which they have to be permitted to modify.

Load Distribution Secondary Without Springs

Somewhere between D and A, as at E, there is a point where the vertical component involved in the turning-movement of B around A as a center becomes so large that it must depend upon the relations between the mass of the whole vehicle and that of the front end whether the movement can be executed or the vehicle will be stopped, as a bumper consisting of curved-up rails stops a train of cars in a station yard. The relation of the masses—which is the same as the load distribution of the vehicle—thus enters into the question of the nature of the movements which will result, but, so far as unelastic vehicles are concerned, this is true only in case of large road obstructions, which have little to do with the main purposes of spring suspension. That the same factor, the distribution of masses, enters strongly the moment springs are used is another matter. On the other hand, speaking of the unelastic vehicle, as the force of an impact, other things equal, increases when a high obstacle is encountered and a relatively large vertical component is required for mounting the obstacle, there is apparently nothing to hinder acceptance of the inevitable conclusion that the force of the impact always automatically divides itself into one force causing a turning movement of B around A, just sufficient to clear the obstacle, and another force which is spent destructively in opposite directions from A and which retards the vehicle and the turning movement.

Perhaps an exception should be noted for the case that the ridge is slippery, so that A affords no reliable fulcrum for the turning movement, but consideration of what will happen in that case must here be deferred.

A Paradox Conclusion

The main theory, which could also be proved by applying the laws for the parallelogram of forces, seems to agree better than the one more commonly accepted with the practical results accomplished in the driving of unsprung vehicles—the shocks being much more objectionable in them than their movements over obstacles—and out of it there arises a certain general and preliminary view of spring suspensions, to the effect that the bounding of spring-suspended vehicles is wholly due to the use of springs while the shocks, if objectionable, are due to insufficient or wrong use of them, and that therefore any improvement looking to the reduction of both bouncing and shocks must consist in the limiting of spring action in some respects as well as to the extension or enlargement of it in other respects.

In motor vehicles the bouncing has, through speed, become as objectionable as the shocks, and the practical development has very properly taken up the work of providing for the limiting of the action as well as for extending the use and range of springs at the same time. But in theory the acceptance of this viewpoint has been less common.

An examination of the movements of a spring-suspended vehicle in passing over the 3-inch ridge of Fig. 3 should show, however, that the viewpoint has a practical value for steering further improvement into the best course. But first the retardations taking place with the unsprung vehicle may be briefly considered for comparison with the smaller retardations usually occurring with the use of spring suspensions.

(To be continued)

Narrowly Averted Famine in Tungsten Due to the War

At the outbreak of war a tungsten famine was threatened in England, and it looked as if it would be impossible for the Sheffield steel makers to supply not only the profitable export trade in high-speed steel but also their home market. Though Cornwall has considerable wolfram deposits, from which tungsten may be produced, and India and other British colonies have illimitable quantities of this raw material, it was found that somehow the method of producing the tungsten had been allowed to become a German monopoly. In the first days of alarm at the shortage, prices ran up to very fancy figures, but have since with the aid of some small imports from the United States dropped to about 5 shillings per pound, which is still twice as high as normally. Two British metallurgical concerns were at once started to provide metallic tungsten powder, and they promise to supply the market adequately in the spring of next year and forever after.

Molybdenum, which can take the place of tungsten in high-speed steels, though the latter is usually preferred, has also become very scarce. For a few years back the Krupps have been buying up this metal, as it is used in the making of big guns.

The first attempts at producing metallic tungsten powder, by the new British concerns, were not wholly successful, but all difficulties are said to have been overcome later.

Tungsten enters largely not only in high-speed steel but also in that used for magnetos, and to some extent in most steels of which extraordinary strength and anti-fatigue qualities are required.—From *The Engineer*, November 6.

Large Radiator Capacity Does Not Mean Efficiency

Ideal Radiator Is Unattainable—Aim Is Lightest Type That Will Do Greatest Amount of Work for Greatest Length of Time at Least Manufacturing Cost—Factors in Radiator Design

By Howard Greer, Jr.,
Chief Engineer, McCord Mfg. Co.

AN IDEAL RADIATOR IS NOT ATTAINABLE. OBVIOUSLY, THEREFORE, THE AIM SHOULD BE TO GET, AT LEAST COST, THE LIGHTEST RADIATOR THAT WOULD DO THE GREATEST AMOUNT OF WORK FOR THE GREATEST LENGTH OF TIME.

There are few if any parts of a car dependent upon so many factors as this one adjunct. It may not be out of place to mention some of the conditions which bear upon motor cooling:

Number of cylinders of motor; diameter of cylinders; length of stroke; speed of motor; whether motors are tight or free running; size and location of water-jackets in motor; dust guards on motor proper; efficiency of motor; efficiency of carbureter; sparking conditions; pump or thermo syphon; total quantity of water in system; quantity of water circulated; size of fan; location of fan; speed of fan; efficiency of fan; whether fan is housed; whether air has straight and free circulation under the hood; frontal area of radiator; efficiency of type of radiator; thickness of core; whether radiator is cased or integral tank; whether hood has louvres; relative size of water tubes and air passages; size, shape and location of air outlets under the hood; efficiency of radiator baffling; temperature of atmosphere; altitude where car is run; humidity of air; skill of operator; opinion of car builder as to amount of cooling necessary; road conditions; speed of car, and the weight of car.

Radiator Demands

Many of the foregoing items are indeterminable, except in specific cases. Therefore, the maxima have to be anticipated by giving the radiator capacity to meet their demands. But what these demands will be is largely a matter of opinion, as, for instance,

Editor's Note—Paper read by Howard Greer, Jr., Chief Engineer, McCord Mfg. Co., Detroit, Mich., before the S. A. E., Indianapolis, Ind., November 10, 1914.

For how many minutes should a car run on low gear, under full motor load, at 10 miles an hour without boiling?

At 15 miles an hour without boiling?

At 20 miles an hour without boiling?

For how many minutes should a car run on second gear, under full motor load, at 10 miles an hour without boiling?

At 15 miles an hour without boiling?

At 20 miles an hour without boiling?

For how many minutes should a car run on high, under full motor load, at 10 miles an hour without boiling?

At 15 miles an hour without boiling?

At 20 miles an hour without boiling?

Mathematics in Cooling

The answers to these questions vary as widely as do political opinions. To put these questions into concrete form: How many British thermal units must be absorbed to satisfactorily cool a given motor working through the full range of possible demands?

After that is decided, then it becomes necessary to consider the arrangement of the car whose motor is to be cooled, and how much of a radiator it will require to dissipate the determined amount of heat, and that means deciding on such points as:

What space is available for the radiator.

Quantity of water to be in the system.

Size and location of the waterways.

Rate at which the water is to be circulated.

Size, location and efficiency of fan and velocity of air through the radiator.

Whether air has sufficient outlet from the hood, and whether the passages are sufficient to allow an unobstructed flow of air through the radiator in its expanded condition.

It is often found that the air conditions are such that in a car speed up to 20 miles per hour the air goes in through part of the radiator and part of the same air comes out through another part of the radiator. The consequence is lack of uniform circulation of water.

Faulty Circulation

Often the bulk of the water circulating passes through a comparatively small section of the radiator core, while part of the water in the core stands still and part actually rises. This is due to irregular cooling, whether caused by the radiator or fan or conditions beyond them. These evils can all be due to causes outside of the radiator, though part of them may be due to improper or inadequate baffling in the radiator itself.

Fan Location

Fans should be so located and so arranged that they will draw air through every air passage of the radiator at the highest velocity commensurate with its cooling values; and to do this the fan must be rotated for its best efficiency. This is usually a rotation so high at low and medium speed of the motor that none of the ordinary pleasure car fans would hold together at motor speeds possible today if the fan belts did not slip.

Capacity Vs. Efficiency

Frequently radiator cooling efficiency is discussed when radiator cooling capacity is what is meant, for it is not uncommon to find a satisfactorily cooled car with a radiator of ample capacity but of abominable cooling efficiency. None the less, this very radiator may have great merit, because of its simplicity of construction, its freedom from clogging, its ruggedness of build and the fewness of its seams.

A radiator 24 by 24-inch, of the .25-

inch cellular type, has about 10,000 lineal inches of seams that must be watertight, while there are tubular types that have but 750 inches of seams that must be watertight. These latter, however, are frequently so inefficient, bulky and heavy that their adoption for pleasure cars is almost out of the question. Therefore, some lighter, efficient, though delicate cellular type is necessary, because of the restricted space available, even though such a radiator costs more and is less durable.

From this important angle, then, it is best to choose the radiator of proper capacity, which has the fewest possible number of places where leaks can occur, always keeping in mind which has the best type of joint.

Don'ts in Construction

Car designs, or demands for appearance, are so restrictive that ruggedness of construction within reasonable limits of cost is today almost impossible.

For structural reasons the following should be avoided:

1—*Shafts should not go through the bottom tank.*

2—*No wrought iron or steel of any kind should be used in a radiator where it comes in contact with water, because of the excessive rusting.*

3—*Crooked inlets and outlets should be avoided. They are expensive to make, difficult to apply and frequently it is impossible to attach them with as many rivets as necessary.*

4—*Long inlets and outlets are objectionable, because if they are strained at all the leverage on rather a weak radiator tank is so great as to probably injure the joint.*

5—*Inlets and outlets or their flanges should always be kept as far away from the edges or seams of the tank as possible, else in soldering the inlet the seam be loosened, or in soldering the seam the inlet be loosened.*

6—*It is always well to have a top tank of not less than 3 inches in depth, so as far as possible to insure always having enough water to cover the top of the tubes. If the radiator is to be used for thermo-syphon circulation the top tank ought not to be less than 4½ inches deep, so as to get a head of water over the tubes and of the extended tank type so as to have sufficient water in the radiator to insure as far as possible always having the tubes covered with an ample head.*

7—*Extended tanks which overhang more than 3½ inches are objectionable, because of the difficulty of supporting them in their overhung position.*

8—*Shallow bottom tanks are objectionable, primarily because they do not, as a rule, present enough surface to which to properly apply the outlet casting.*

9—*Radiator holding down studs should be on the center line of the center of gravity of the radiator when it is in its working position and of such a distance apart that if the lower tank deflects at all the deflection will be no greater between the studs than beyond them and vice versa.*

10—*Often for the sake of design the frontal shape of the radiator is such as to necessitate the use of side tanks in the top corners, and in some instances also side tanks in the bottom corners. Such an arrangement increases the number of joints in the radiator and introduces the tubes into the tanks at such an acute angle that making and maintaining them tight is very difficult.*

11—*Where possible it is best not to have a hood ledge offset greater than 1-8 inch, because of the difficulty of getting material for casings that will stand greater offset.*

12—*Core face offset of the radiator casing had best be never over 1-4 inch deep, on account of the difficulty of drawing such frames.*

13—*When a casing is made with too much taper great difficulty is encountered in the drawing, and the expense of the drawing tools runs up enormously. Frequently many thousands of dollars on radiator casing tools could be saved if a few comparatively insignificant angles and tapers could be brought within mechanical limits.*

Rivets, Then Solder

All castings that are to be soldered to a radiator should be held in place by rivets and applied to the flat face of the sheet where possible, always avoiding going around the corners.

To properly solder two metals, they must both be of such a heat as to bring the solder to its greatest fluidity and, obviously, any parts that are not in such contact as to prevent the solder running through their joints are not properly fitted. A radiator should be so mechanically constructed that it will hold together without any solder, and thus leave the solder to perform the function of a gasket.

Solder is a weak soft metal that crystallizes readily under vibration, but makes an excellent gasket if it is not strained in holding parts together.

Mounting the Radiator

The failure of radiator joints is by no means an indication of poor workmanship or improper design. Often the member employed to support the radiator is inadequate, and sometimes troubles from poor supporting are augmented by unnecessary hood strains through the kind of latches used or strains brought about by the inlet and outlet being connected to the motor, while the radiator itself is mounted upon the frame of the car.

To properly mount a radiator a suitable support or suspension for the particular design must be provided or else the proper design of radiator for the supports available must be selected. If a radiator is to have stud mounting, its bottom tank reinforcement should rest upon soft pads which will retain their elasticity, and these pads should never be over 2 1-2 inches by 2 1-2 inches and should come between the tank and the supporting member on the car. This member must deflect a minimum and twist the car frame rather than be twisted by it if you want to save the radiator.

If the car design requires a trunnion or bracket support attached directly to the frame channels, it is advisable, if not essential, to have the road strains come upon a separate casing into which the radiator proper is bolted, so as to save it from the direct road shocks.

Enamelling Problems

As cars have become lighter and more flexible, more demands have been put upon the radiator, and as in America where the blue black body colors have become popular, it is necessary to match them with the radiator, and to do this and have the finish last it is necessary to enamel by baking. To enamel satisfactorily, without injury to the soldered joints, a detachable casing which may be baked at a temperature which would injure soldered joints is desirable.

Since there are so many limitations imposed upon the radiator manufacturer by materials, tools and the ability and class of labor to be had, it would doubtless be of mutual benefit to both the manufacturer and the car builder if they would, in every instance before a radiator is needed, get together for mutual assistance and exchange of views.

Radiator Suits Car

Every car should be fitted with a radiator particularly designed to meet the cooling conditions encountered, and should be constructed in such way as to meet, as fully as possible, the strains which may be brought upon it through its particular method of support.

Materials for Radiators

In the selection of materials for radiator construction great care must always be exercised to insure their being proper for the work required. Brass must be free from defects and of proper hardness or softness, dependent upon the purpose for which it is to be used. The percentage of tin in the solder must be different for the different kinds of work the solder is to do, and the castings, particularly those that are to be watertight, must be made and tinned with the greatest possible care to insure their not rusting out and that they will always be tight.

The internal baffling in a radiator is of great importance, particularly because the water almost invariably enters the center of the top tank and goes out of but one corner of the bottom tank. If the baffling is not such as to insure the proper distribution of the water in the top tank so that it will go down uniformly through the radiator, in spite of the fact that it is taken out irregularly at one end of the bottom tank, then the baffling is not correct.

Locating Baffles

And if it happens that the fan to be used in conjunction with the particular radiator takes its air through the core in such way as to cool it more in one section than in the other, then the baffling should be arranged so as to pass through this section of the core a proper amount of water to insure obtaining the highest total efficiency from the apparatus.

The radiator cap has been a subject of much discussion and great variety of design, and today it has reached the point where practically all caps have their threads on the inside, so as to save them from abrasion if they are dropped, and this puts the thread in the filler tube on the outside tc save it from abrasion from funnels, etc., used in filling the radiator.

The finish of the cap varies from the condition left by the sand in the mold, through polishing and plating, up to coatings of hard rubber or Bakelite, which latter is a synthetic rubber made from carbolic acid and formaldehyde, and a pigment to give it color, and an asbestos or wood fiber filler to give it body. It has many characteristics which make it more valuable for the purpose than hard rubber. Its cost is about the same as gutta percha. It is somewhat stronger, though a little less elastic; will withstand all the heat that can ever be brought upon it in a radiator cap. It takes a high polish, and has the merit of not bleaching out.

Protect Filler Screen

An important part of a radiator is its filler screen, and yet it is frequently not used, or if it is left in the filler tube, it has a hole punched by a funnel, which makes it ineffective. If users could be made to realize the importance of straining the water that goes into the radiator, they certainly would take much better care of the screens.

In the city of Detroit a radiator, presumably using nothing but city water, was so clogged in 6 months, that in a thermal test it showed a dissipation of only about 720 B.t.u.'s; but after its core was removed and thoroughly cleaned, and the radiator rebuilt, the same radiator in its clean condition dissipated 1100 B.t.u.'s.

The overflow tube which is usually looked upon as an unimportant adjunct, not infrequently is the cause of much annoyance, for should a slight leak occur where this tube enters the tank, the water will flow down the tube on the outside, giving all the appearance of taking care of an overflow from an over-full tank; while as a matter of fact, the tank may be nearly empty.

On the other hand, very frequently a radiator which is far from full, but is improperly baffled, swirls its water in its top tank, so that a large portion of it is lost down the overflow, unless the overflow tube is closed at the top and the vent hole into it put on the side up against the inside of the filler tube.

Water Surging

Even though a top tank be properly baffled, for the distribution of the water, it is not at all certain that it is properly baffled to prevent surging, which almost invariably occurs when a car is started or stopped suddenly. In one instance a car was driven over country roads at an average speed of 26 miles an hour for 1 hour and 10 minutes, and lost no appreciable amount of water, either through evaporation or lost down the overflow tube. But 3 pints of water were lost in the next 30 minutes by the same car, which was driven through a highly congested district of a large city, where the stopping and starting was very frequent, for every time this car started and stopped, the water swashed, and some ran out at the overflow.

Testing Radiators

Testing apparatus for determining the relative efficiency and capacity of radiators is comparatively inexpensive and easily had, and invaluable to both the car builder and the radiator manufacturer. The best type of apparatus consists of some kind of water heater with thermostatic control, a pump and a meter to measure the quantity of water circulated; scales to weigh the total quantity of water in the system; thermometers to take the temperature of the inlet and outlet air, and the inlet and outlet water; variable speed motors which can be set at a wide range of speed for both pump and fan; humidor to maintain a standard humidity in the testing room: airometer for taking the velocity of the air through the radiator, and tachometer by which to register the variation in the speeds of the motors due to change of voltage of current. And by thermal calculations it is not difficult to tell the number of B.t.u.'s dissipated in a given time by a given radiator under conditions held practically constant and standard.

In testing radiators for capacity, it is necessary to compare them with some known standard. Such a standard can be easily established by taking a car which acceptably cools for every one, and running it with a given load, a given distance up a certain hill on its different gears,—first at 5 miles, then 10 miles, then 15 miles, then 20 miles per hour, starting each time at the bottom with the water in the system about 120 degrees, and noting the rise in temperature when the car finishes its run, which run should not be less than a mile.

By making this series of runs on various gears and at various speeds, it is possible to establish a standard by which to compare other cars' performances.

Glass Radiators

Observing circulating water carrying fine sawdust in a glass radiator, a number of interesting phenomena appear which are valuable guides in pointing the way to proper baffling and proper fan location, for to get the best capacity out of the radiator, it is necessary to have a suitable proportion of the water passing through the zones of the radiator, through which a given quantity of air travels. And if these proportions are not obtained, and there is either an excess of air, or such an excess of water that the proper amount of heat is not absorbed, the circulation is immediately affected.

There have been radiators constructed in which the water was made to circulate through horizontal passages a number of times across the face of the core. These have the objection of being difficult and expensive to construct, and more or less difficult to drain. There have also been radiators constructed in which all the water went through a series of passages on the back of the radiator, and up through a series of passages in the middle of the core, and down through a series of passages at the front of the core. Such a radiator has a cooling advantage over the straight-flow type, showing, in some instances, more than 8 per cent. increased capacity.

The larger the quantity of water is in a cooling system, the more uniform can the temperature of that system be kept. Quantity is particularly advantageous in hill-climbing, on the principle that it takes longer to boil a big teakettle than it does to boil a small one.

Thermostatic Control

From a purely theoretical standpoint, thermosyphon system of cooling is best, but in actual practice such a system, restricted in its application as it must be on a motor car, does not fulfil expectations on account of the wide range of demand put upon it. The time is probably not far distant when cars will be equipped with some type of thermostatic control in their cooling system, so as to maintain the water in the motor jackets at as nearly a constant temperature as possible, irrespective of the work the motor is doing. And it is not beyond reasonable expectation to anticipate the introduction of an effective and cheap fan regulator which will assist in this thermostatic control, by furnishing the proper proportion of air to cool the water to the required degree.

A Testing Plant for Spark Plugs

Toledo Firm Has Experimental Department for Improving Manufacturing Methods, Etc.

UP in an isolated part of the top floor of the big plant of the Champion Spark Plug Co., Toledo, O., where 25,000 spark plugs are born each day, they have an experimental and testing department which would do credit to a motor manufacturer, to say nothing of a concern which does nothing but make the small, but essential, spark plugs that cause the firing of the charges in an engine.

To the average automobilist, a spark plug is simply a little device which brings two terminals of an electric circuit close together so that a spark can jump from one to the other and thus ignite a compressed charge of gas. But to the specialist in this line it means more. He knows it to be a highly perfected article which he is constantly trying to improve by testing and experimentation.

A spark plug is subject to a number of maladies. It may be given to prematurely igniting the charges; it may be so constructed that there is not the hot spark necessary to greatest power; it may develop leakage under compression and heating.

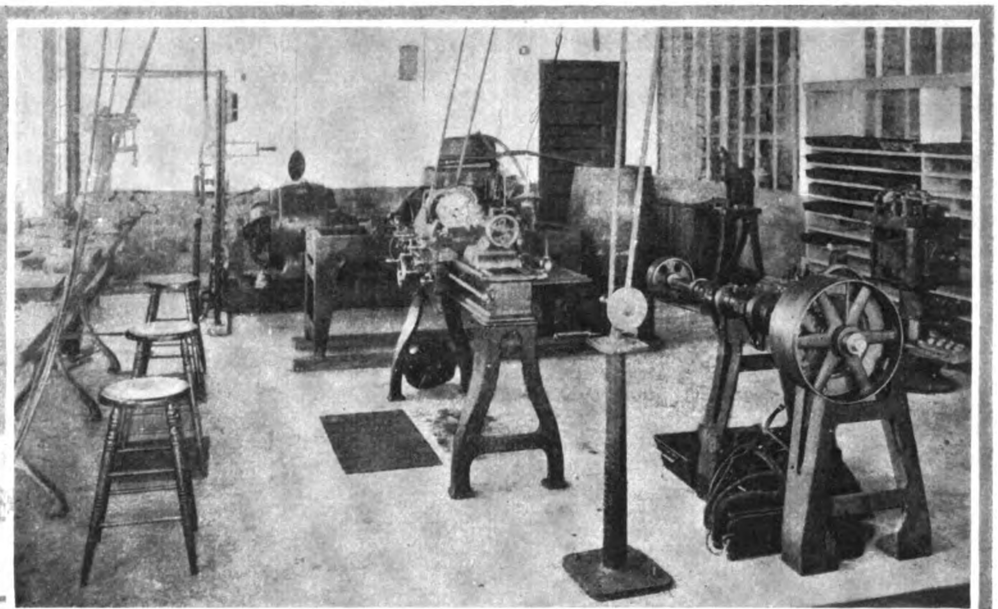
It is primarily for studying the effects of various factors entering into the ignition problem and for purposes of comparing the power output of a motor equipped with its plugs and with other makers' plugs that Champion has installed this new department which is in reality a miniature machine shop and testing room.

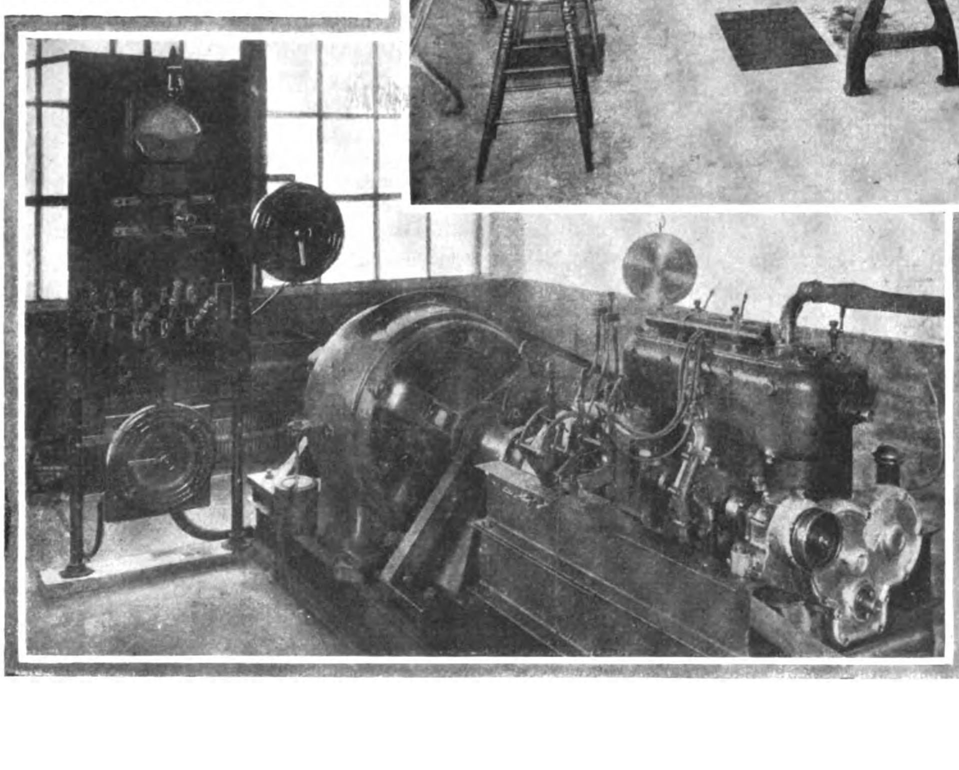
There is a complete electric dynamometer set with a capacity of 70 horsepower which is driven by a gasoline engine tuned up so as to run as high as 2,000 revolutions per minute. The factory simply regards this engine and equipment as apparatus to try its plugs out on. The generator is a Sprague, rated at 42 1-2 k. w. at 1,800 revolutions per minute. It operates with 250 volts and the amperage is 170. In addition to this apparatus there is a separate gasoline motor used only for idling tests, to say nothing of the lathes and other machine tools.

This experimental department is constantly at work on the development of new machinery to lessen the labor cost throughout the plant. For instance, at this time it is working on an automatic electric welder which will do away with the present method of welding by hand. When perfected, this complicated machine will automatically feed the spindles and wires to be joined to make the center electrodes of a plug, the sparking point being platinum and the main wire steel.

If any new type of plug is developed, it falls to the lot of this recently established section of the Champion works to devise the best and cheapest method of making it. Consequently it is made in this department in all the possible ways, and the best of them decided upon as the method to recommend to the manufacturing departments.

Every so often a batch of the regular run of plugs is taken at random from the product coming through the factory, and these sent up to the testing department. Here they are first put on the gasoline engine, with its electric dynamometer for load, and tested for all conditions of running. Then they are set in the idling motor and run some more, this idling test being the hardest to which the plug can be subjected.

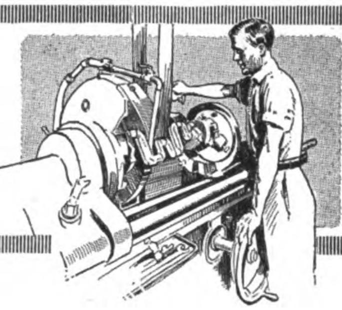




Above—A corner of the testing and experimental room of a concern making only one thing—spark plugs. In this department are all machines necessary to development of new machinery; to the production of a spark plug, etc. Here any new plug is first made and best methods of manufacture worked out before it is turned over to the manufacturing department for production in quantity

Left—A complete electric dynamometer testing outfit used only in testing spark plugs. The gasoline engine is capable of 70 horsepower and is tuned to run as high as 2000 r.p.m. Thus almost any motor operative conditions are obtainable and plugs can be observed when firing the motor under any of these conditions

The Rostrum



This department is for the instruction of the readers and all are at liberty to ask questions. Be sure to give full name and address that we may send you a reply by letter if there is no space in the Rostrum. If you wish to sign a fictitious name, also sign your own.

Claims Cyclecar Is Still the Future Means of Transportation

EDITOR THE AUTOMOBILE:—Before the ashes are sifted over the grave of the sporadic cyclecar movement of 1914 (as is being suggested in some quarters), a few words might be of interest from one who has studied these sporadic cyclecars, ridden in several, nursed the troubles of one of the most troublesome, and still believes more strongly than ever that the pure cyclecars developed within the past year are nearer to the future means of light transportation than any other type yet constructed. The cyclecar here referred to is the vehicle defined by the original limits of 71 cubic inches displacement and 750 pounds weight, with the usual principles of two air-cooled cylinders, friction or planetary transmission, belt or chain drive, light rear axle, narrow tread and tandem seating.

The motor-buying public is now in a different frame of mind than when the automobile and motorcycle came out. The motor vehicle of the present day is no longer a toy to be taken out to see how far it will run; it is a means of getting somewhere. If the early automobiles had been judged by this standard, they would have died much sooner than the cyclecars have. But they were given time to develop, and the successes of the present are built on the failures of the past. This does not prove that cyclecars should be made and bought whether they are reliable or not, but it suggests that they may not yet be permanently dead just because many of those hitherto built have been far from trouble-proof.

A few of the facts and accomplishments of the cyclecar may be enumerated, lest we forget: They have been driven at speeds higher than practicable in any but the highest-priced automobiles, over rough and rutty roads, with extraordinary comfort to the occupants, at a fuel economy of over 40 miles per gallon (my own experience without any special adjustments or economizers), and a tire economy and reliability represented by a weight of less than 250 pounds per tire, in a car requiring much less attention in normal use (lubrication, tire work, etc.) than the ordinary automobile.

There has been a noticeable absence of dangerous accidents, in spite of the flimsy construction employed on many of them. Cyclecars do not turn turtle.

If it is claimed that flimsy construction is a necessary companion of light weight, we have but to refer to the motorcycles, which, laden down with heavy equipment, so strong that they can carry up to six passengers, weigh less than half the standard cyclecar figure of 750 pounds. In fact, there are few of the objections advanced against the cyclecar which do not apply with equal force to the motorcycle.

The cyclecar has been regarded as an automobile made up of freak parts, when it is really constructed of parts already absolutely standardized, partly in automobiles, and partly in motorcycles. I do not know of a principle or device used to any extent on the cyclecars of the past year which has not a long and honorable record in either the two- or four-wheeled field, with the possible exception of two which are by no means representative.

Why then have the cykes been brought into disrepute? Not because air-cooled V-engines are bad—they are still standard on motorcycles. Not because friction transmissions are bad—they won the 1913 Glidden tour. Not because the narrow tread is bad—such statements are made only by those who have never tested it. Simply because the correct combination of these features requires better engineering than has been put into it in most cases. Because the field has been invaded by get-rich-quick parties, and the movement fought by both the motorcycle and automobile interests, and because if any company has yet invested the necessary large capital in the right way to bring out a real cyclecar, it has not yet reached the publicity stage.

Tandem seating is perhaps the hardest pill for the average motorist to swallow. It is not a necessary cyclecar feature, but it will be better liked with an increased appreciation of low centers of gravity, center drive, and the handiness of the narrow tread in traffic.

The writer believes on the whole that the supposed objections to the cyclecar type are not fundamental, and would like to read expressions of others on this question.

H. KURTZ RANDALL, M.E.

Best Position for Spark

Editor THE AUTOMOBILE:—1—In four-cycle internal combustion motors is there an exact relative time at which the spark should occur to produce the highest efficiency of the motor? In other words, what is the correct relation in degrees of spark advance or retard to the speed of the motor?

2—Should the advance or retard of the spark be in absolute (predetermined) synchronism with the motor throughout its entire range of speed?

3—Which will give the best results for general road driving, an automatically controlled or a manually controlled spark, and why?

4—In an electrically equipped car, is there any logical reason for having two electric generators? One supplying current to the storage battery for lighting and operating the cranking motor; the other for generating current for the ignition system?

5—Under all conditions is a magneto spark as efficient as a spark obtained from a storage battery?

6—For general touring purposes in a mountainous country over all kinds of roads, which is the more efficient and economical: A small-bore, long-stroke, high-speed motor, or a larger-bore, shorter-stroke, slower-speed motor, both having the same relative horsepower and operating under the same load conditions? What, if any, advantages has the one over the other?

Bloomsburg, Pa. C. S. Van Horn, D.D.S.

—1—Yes, there is a time when the spark is most effective but it is impossible to state this in degrees because it depends on the size and shape of the combustion chamber, the speed of the motor, the mixture, the compression, the location of the spark plug and the intensity of the spark.

2—No. The advance should vary roughly according to the speed. At low speeds the spark should be retarded and at high speeds it should be advanced. In any case less advance is required as the throttle is opened because the speed of combustion increases with the working compression which depends directly on the amount of throttle opening.

The necessity for advancing the spark is brought about by the fact that it takes a definite time to produce the spark, that is, from the instant the breaker points separate on the magneto until the spark occurs in the cylinder a small amount of time is consumed, this interval being the same whether the motor is running fast or slow. Therefore, if the magneto is set to give a spark just on dead center when the motor is running 300 revolutions per minute then the spark will occur too late when the motor is operating at 2,500, for the speed of the motor has increased eight times yet the interval in which the spark is produced has not been reduced at all. It is to compensate for this lag that the spark must be advanced as the motor speed increases.

3—This is an unsettled question. For the automatic spark control it is argued that the average driver is not sufficiently skilful to set the spark lever in the place for best efficiency under different conditions of driving and that therefore the set spark is superior.

Those in favor of the manual control generally admit that the automatic control is preferable for the unskilful driver but for the experienced motorist better results can be obtained from the hand control.

4—Some makers believe it better to have the ignition system independent because there is a greater safety factor.

5—See The Automobile for December 3, page 1020.

6—The advantage of the small-bore, high-speed motor is that it is more economical and lighter, on the other hand it must be somewhat noisier perhaps the noise is not appreciably greater, and it may not stand up as well although this is largely a matter of design.

Two-Story Garage Design

Editor The Automobile:—Kindly give me a layout for a two-story garage, 60 by 100 with elevator.

Little Falls, N. Y. C. F. Ross.

—The plan of your garage should largely be determined by what you desire to use it for, and although you are not an architect, you, probably better than anyone else, can select the best plan. First of all decide just what you desire to use it for. Are you going to have a supply store in connection with it, and will you need a salesroom for cars? Will your repair trade be heavy? When you have all the facts governing the design of this building before you, you can easily make a plan that will be found suitable and convenient.

Fig. 1 shows a plan that will be found good. In this design it is assumed that you are to run a supply store but not a salesroom. The office and store are put at the front of the building along the street. Directly back of them is the stairs which may be reached conveniently from the office or the main floor of the garage. In the other corner at the front is the elevator, which may be entered from the street as well as from the main floor of the garage. The elevator should be made large enough to take the largest pleasure car comfortably but need not have capacity enough for trucks as any of these you may have may be stored on the ground floor.

At the rear of the main floor, extending all across the back is the repair shop. The machine tools are grouped at one side, and the forge is placed against the wall. There is a bench along the back wall where the light is good and the rest of the space is for accommodating the cars that are being repaired.

Ignition Current Negligible

Editor The Automobile:—1—When using a six-cylinder automobile engine of 2.5 bore by 5 stroke, with two 15-candlepower, 7-volt headlights switched on full, one tail light and one dash light, each 4 candlepower and 3.5-volt, what proportion of the total current being drawn from storage battery is consumed for ignition of the engine.

2—Is the amount of current consumed for ignition constant or do different engine speeds or different road conditions cause it to vary?

3—What is the approximate saving in current when using the two headlights switched on as dimmers instead of switched on full?

4—Which furnishes the hotter spark at slow engine speeds—a storage battery or a high-tension magneto, assuming both are working efficiently?

New Orleans, La. D. Williams.

—1—The proportion of current is negligible.

According to some data given on page 1021 of The Automobile for December 3 the average battery spark has an ampere flow which reaches a maximum of .04. The shape of the wave is triangular, therefore the average flow is one-half this or .02. The time is .006 seconds. Assuming that the motor is running 1,000 revolutions per minute, 1,500 sparks are generated. Therefore the average current flow during 1 minute is $1{,}500 \times .02 \times .006 \div 60 = .003$ ampere.

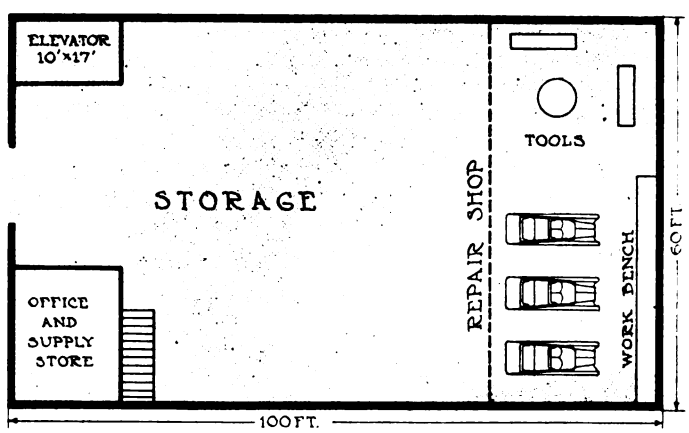


Fig. 1—Plan of ground floor of public garage 60 by 100 feet

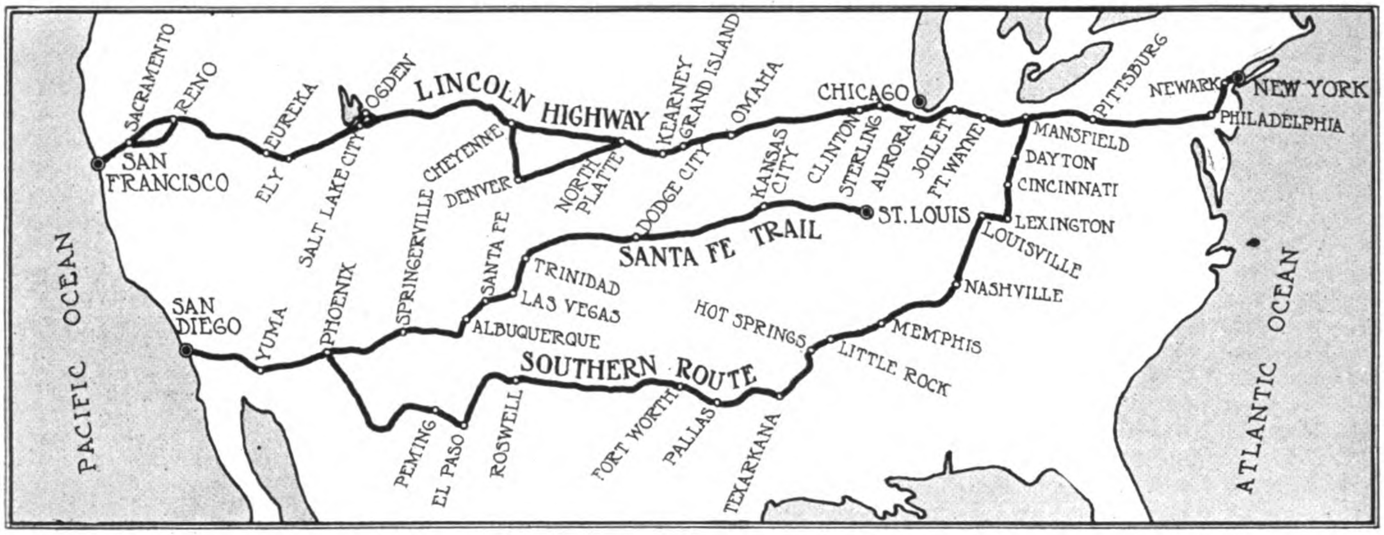

Fig. 2—Three routes to the Pacific Coast: The Lincoln Highway, The Santa Fé Trail and the Borderland or Southern Route

2—The consumpfion of current is proportional to the motor speed—for instance, at 600 revolutions twice as many sparks are required as at 300. However, no more current is required to produce a single spark at 600 or 3,000 for that matter than is required at 300.

3—This all depends on the method of dimming used. If the lamps are dimmed by connecting them in series, then the current consumption is cut in half if the resistance in the wires is neglected, and since this is small it may be. If two bulbs are used in the headlight, a large one in focus for country driving and a small one out of focus for city driving, the saving may be much greater, the small bulb taking about one-fourth the current of the large one.

4—Under favorable conditions there should be little difference.

Heavy Car Requires Large Motor

Editor THE AUTOMOBILE:—I am considering installing a new power plant in my seven-passenger car, 128-inch wheelbase, weighing 3,450 pounds and with gears adapted to 45 horsepower. What size motor would you advise for all-around service especially where roads are sandy and hilly, generally rough going?

Would the economy of say a 4.25 by 5.25 be offset by more lower gear running or would a 5 by 6 even with greater gas consumption give more general satisfaction?

Springfield, Mass. W. B. S.

—A motor measuring 5 by 6 would give an excellent performance and would certainly be advisable unless the increased gasoline consumption is objectionable. If you adopt this motor be sure that it is not too powerful for the transmitting mechanism because if it is it may cause undue wear or breakage. Again, there may not be room to place a motor of this size in the chassis.

The 4.25 by 5.25 motor would be rather small although there are many cars of this size using a motor no larger.

Possibly the most satisfactory would be a 4.5 by 5.5-inch motor. It would not unduly strain the parts, its gasoline consumption would not be too great and yet it would develop power enough to satisfy most motorists.

Fire Comes from Cut-Out

Editor THE AUTOMOBILE:—Please advise me regarding the following: I am troubled with fire coming from the exhaust cut-out underneath my car when running rapidly and shutting off quickly. Also when pulling hard. It is not the regular exhaust from the engine, but a large blaze like gasoline fire which comes clear to the ground and spreads out several feet each way.

I am at a loss to know whether or not I am using too much gasoline or whether the valves are not seating properly, or whether too much lubricant, which comes through and catches fire?

Petersburg, Ill. I. R. ABBOTT.

—It is difficult to say exactly what is causing this trouble without seeing the car. However, it may be that the valves are improperly timed or the mixture may not be correct. If the valves have been reset lately it would be wise to make certain that the timing is correct, but if they have not been reset, they probably are all right.

If the mixture is at fault it is a simple matter to adjust the carbureter.

Possibly there is carbon in the exhaust pipe or it may be that you are running with the spark too late.

How to Mix Graphite with Oil

Editor THE AUTOMOBILE:—1—We have a 1912 car that has a unit power plant using one grade of oil for crankcase multiple disk clutch and gearset. The oiling system is circulating splash with pump, and we understand that some car owners put graphite with the cylinder oil for better lubrication. Can we use graphite in our power plant? If so, how much graphite to the gallon of cylinder oil and what make of graphite is the best?

2—Will graphite make the clutch slip and is the use of graphite in the power plant good practice?

Rockland, Me. E. O. P.

—1—Us one teaspoonful of flake graphite to each quart of oil. Do not throw the graphite in loose, but mix it into a soft paste first and then add it to the oil. In buying the graphite be careful to obtain a good motor graphite as some graphites are not suited for motor lubrication. Some are too coarse, others too fine and some contain grit. Therefore, be certain you obtain a good motor graphite.

2—The graphite will not make the clutch slip. It is generally considered that the use of flake graphite will improve lubrication by cutting down friction and reducing wear.

Abbott Gearing 3.5 to 1

Editor THE AUTOMOBILE:—1—Please tell me the gearing when on direct drive of our 1913 Abbott, seven-passenger touring car, model E 44-50. We use 37 by 5-inch tires.

2—What is the maximum speed?

3—Which is the more nearly correct horsepower rating; the S. A. E. or the A. L. A. M.?

4—Our motor has a bore of 4.5 and a stroke of 5.5 inches. What is the S. A. E. and the A. L. A. M. rating of it?

5—When either of the axle shafts are removed from the rear wheels the wheel can be wabbled around on the bearing. Schaffer annular ball bearings are in the wheels. Please explain why this happens?

New York. LAWRENCE A. DIETZ.

—1—The gear ratio is 3.5 to 1. The size of the tires has nothing to do with the gear ratio. The gear ratio is the ratio between the size of the bevel pinion and crown gear in the rear axle. The size of the tires has an influence on the maximum speed that may be obtained but it is not connected in any way with the gear ratio. If bicycle practice were followed we might obtain a figure representing the total gearing by multiplying the size of the tire by the gear ratio, but this is never done.

2—The maximum speed is between 50 and 55 miles per hour.

3—These two ratings are identical. When the A. L. A. M. went out of existence several years ago, the name S. A. E. was gradually given to the rating as this method of figuring horsepower was recognized by the Society of Automobile Engineers. The A. L. A. M. formula was imported from Great Britain where it is known as the R. A. C. or Royal Automobile Club formula.

The formula in question is, horsepower $= \dfrac{D^2N}{2.5}$, where D = bore in inches and N = number of cylinders.

3—Answered above.

4—The S. A. E. rating is 32.4.

5—This is as it should be. A certain amount of play is allowed when the shafts are removed. As long as the shafts are tight there should be no play, however.

Three Routes Offered to Pacific Coast Tourists

Editor THE AUTOMOBILE:—I am figuring on touring out to the Panama Pacific Exposition next summer and one of the things which will determine whether or not I make this trip is the length of time involved. I would, therefore, be glad if you could inform me on this point and perhaps map out a route. Some of the readers who have made extensive tours might be able to offer information in regard to the eastern conditions and also the much more valuable suggestions relating to the equipment of a car. I would like to hear from readers on this latter point as many others who are going and expect to make their car their hotel, might be able to obtain valuable information through your columns.

Cleveland, O. READER.

—You might make the trip in 1 month although this would be traveling fast.

Details concerning the different transcontinental routes and other information regarding the trip are given below, the material being taken from the Automobile Blue Book.

Only conditions west of the Mississippi River will be taken up. In point of road conditions, accommodations and supplies this article might be restricted to the territory west of Kansas and Nebraska, for under ordinary touring conditions met with in the summer there is probably no section where better time can be made than on any of the well-known routes across Iowa, Missouri, Nebraska and Kansas. Although the distances between towns are a little greater than on most of the routes east of the Mississippi River, plenty of accommodations and garages will be found along these routes to answer the needs of the most exacting motorists. The only precaution at all necessary is that in western Kansas and Nebraska during midsummer it is advisable to carry a full African water bag at all times simply for the comfort of the tourists.

Just as soon as the motorist goes west from Cheyenne or Denver it is advisable to make a few other additions in equipment and supplies. If there are four in the party at least two water bags should be carried, as some cars will need an extra supply of water for radiator in climbing to higher altitudes or in hard pulls through sand. It is always well to be prepared. Also some food supply should be carried at all times, with a blanket for each one in the party: another thing, warm clothing should be provided, for with the sun below the horizon the temperature drops very fast in high altitudes, and the nights are surprisingly cool even in the summer time.

If everything goes all right, as it does with the majority of tourists, the trip will be comparatively easy, but if breakdowns or stops due to lack of gasoline occur, as they sometimes do out in the barren places, then serious results are sure to happen unless there is another car in the party to go back for supplies, which may be thirty, forty or fifty miles distant. Such long stretches with hardly a habitation occur on any transcontinental route in some part or other, but even these are no drawbacks in themselves to the trip if, as stated above, proper precautions are taken not only in supplies and equipment, but that the tourist drive in accordance with local conditions.

Going west from Cheyenne along the Lincoln Highway little difficulty will be found in crossing the Continental Divide, for the rise is gradual, and many people will not know when they are crossing the backbone of the continent. For the most part southern Wyoming offers a very good natural road material of a gravelly dirt in sufficient quantities to surface the whole road. This is being done rapidly; moreover, the fords and dry washes are being bridged, especially those that may have given difficulty a year or two ago. West of Salt Lake City or Ogden there is a choice of two routes. There is a short line along the route of the Lincoln Highway to Ely, but this presents two difficulties. First, this route, although shorter than the northern one, crosses one of the most barren parts of the Great American Desert, and soon after leaving Salt Lake City practically no habitation of any kind is encountered for over eighty miles, but for present conditions the northern route around Great Salt Lake is to be preferred, as it follows for the most part the line of the railroad, accommodations are more frequent, and as a whole road conditions are better. Both of these routes join at Eureka and continue west, with generally good going into California. Natural road conditions in Nevada are excellent, and soon after entering California modern improved roads are followed to the Coast.

Where the Scenery Is

The above route, which for the most part is along the line of the Lincoln Highway, will probably receive the greatest amount of travel, but to those desiring to get the full benefit of a trip in the West little opportunity is given of seeing Rocky Mountain scenery. To those who have a little more time and like magnificent scenery, the trip across Colorado offers wonderful possibilities. The most serious drawback to this route is not the road conditions in Colorado, but the conditions after the Colorado line is crossed, and from there most of the way into Salt Lake City. The desert must be crossed for nearly two hundred miles. Those who by experience and equipment are prepared for such a trip will find the scenery of Colorado well worth the slightly increased hardships of crossing Utah.

To those desiring to follow the more southern route there are two optionals presented, the best known being the Old Santa Fe Trail, which continues westward along the route of the Ocean-to-Ocean Highway across New Mexico and Arizona. Here again the Continental Divide is crossed so easily that the stranger would have to be told the exact point of highest altitude. The route for the most part, especially across New Mexico, has received a great deal of improvement, and accommodations and supplies are of just about the right interval for each day's run. In Arizona one or two sections are still in need of improvement, but this is going forward rapidly and really no serious difficulties will be had on the trip as far west as Phœnix. From there on greater caution should be used in both equipment and driving, although as far as Yuma quite frequent accommodations and supplies are to be had. The short stretch between Yuma and El Centro is the most difficult part of the southern route, and really no permanent location has been determined for this link at present.

The other route spoken of as a southern link for transcontinental travel is one of the latest developments, known as the Borderland Route, which leaves the Old Santa Fe Trail in western Kansas, going through the Panhandle of Texas and crossing southern New Mexico and Arizona. Due to the mining industry the southern portions of these two latter states is being developed very rapidly with corresponding road improvement.

June the Best Time

If going by the central routes, about the only practical time is between May and the latter part of September, and even then if it happens to be a late spring with heavy rains conditions may not be favorable, and it is really best not to leave until after the middle of June, taking the trip as a whole. There is also a possibility of early storms in high altitudes even in September, although many years the routes are open clear to late October. On the southern route, if not starting too late so as to get west of Kansas and Nebraska before the fall rains set in, the route across Arizona and New Mexico can be traveled almost any month in the year, probably the best time being in September, October and November. The spring is also good, as the rainy season there is in July and August. The objection to the summer months is not so much on account of rain, which is quickly over in that part of the country, but on account of the exceedingly warm days.

In tire equipment it is advisable to have practically new tires all around, and two extra casings with about four tubes. Take a few small repair parts that you have found from experience to be of most use on your particular car. Above all do not try to take along enough to rebuild the whole car. Remember that extra weight is the worst possible thing you can carry. This brings us to the all important point of **keeping the load light**. Remember that, no matter how large or powerful the car it is just as bad to have it overloaded as it is a light car.

There are only a few sections where an extra provision is at all necessary in the way of gasoline, although some people find it advisable to provide an extra tank. Usually one or two 5-gallon cans are sufficient for any emergency.

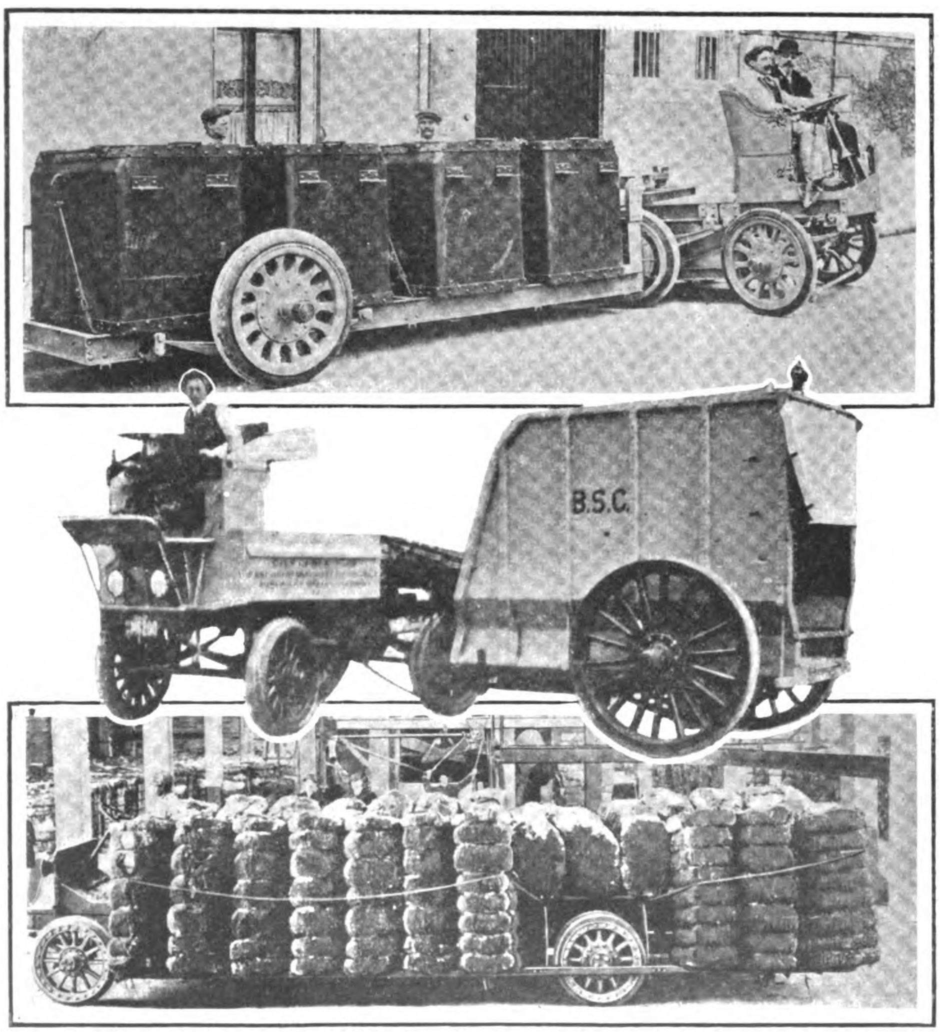
It is always advisable to have a one-gallon can of lubricating oil. There is no telling when this will come in handy. At least two two-gallon African water bags should be provided. These can be hung on the outside of the car, and it is surprising to find how cool the water will remain no matter how hot the sun. It is important to remember that in filling the water bags make inquiry from local people whether the water is good to drink or alkali. A little of the latter will not hurt for radiator use, but it is very disagreeable to the average constitution.

The most useful thing not only for sand, but because it comes in handy for other things, is 100 feet of 1-inch manilla rope.

Two-ton electric lumber tractor with trailer. The batteries are situated in a single front compartment and the lumber is mounted on a two-wheeled truck. The old and new methods are contrasted

Commercial Electrics for Special Needs

Electric Vehicles for Hauling Lumber and Cotton; for Freight Handling; Road Making and Garbage Disposal



Upper—The modern way of collecting garbage. The low frame allows easy loading
Middle—Five-ton electric street cleaning tractor made by the General Vehicle company for use in New York City
Lower—Six-ton electric built especially for moving cotton. Loading is facilitated by the underslung frame

THE adaptability of the electric truck to individual needs is well illustrated by the accompanying photographs which show electric machines in various lines of work. There are tractors for moving lumber, and for hauling garbage and refuse; electric street sprinklers, and road makers equipped with crane and roller; an electric curb-laying machine; small freight trucks for transporting goods from freight car to delivery truck and for carrying goods from department to department in large factories; there are underslung trucks for carrying large loads of cotton, and many other types.

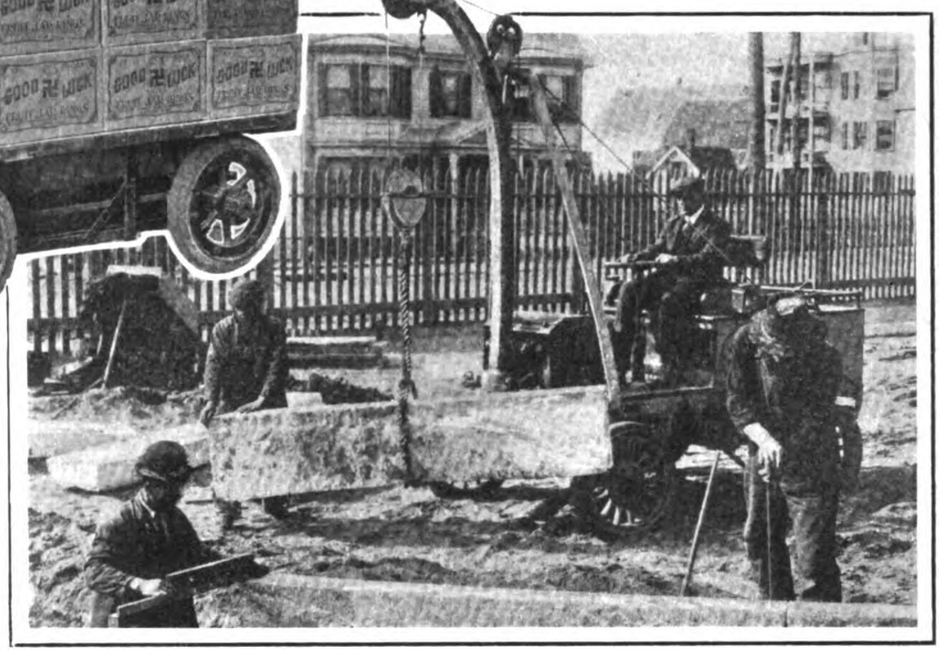
Consider the handling of cotton, for instance. Down in Savannah cotton is moved by electric stevedores across the great piers into the holds of the steamers which take it North. At the Bush docks in Brooklyn the same cotton is placed in freight cars by battery truck cranes. It is taken out of the cars at the mills by industrial trucks and moved to storage and then to the spinning room by them. Later the bobbins, dye tubs, and beams are moved from mill to mill by small electrics, while in the mill yards the 2 and 3.5-ton trucks are delivering supplies or loading finished goods.

The building of special trucks began over 10 years ago, although rapid development has only occurred in the past 6 years. Electric coal trucks with hand-operated dumping bodies appeared in 1902 and winch-equipped trucks for handling safes in 1903.

NOTE — The accompanying illustrations and information are taken from the paper entitled "Special Applications of the Electric Truck" read by F. Nelson Carle before the Electric Vehicle Assn. of America at the convention held in Philadelphia October 19-21.

Top—Fleet of 1-ton electric freight trucks. It is these machines that allow the rapid handling of freight, thus relieving congestion and providing greater freight capacity

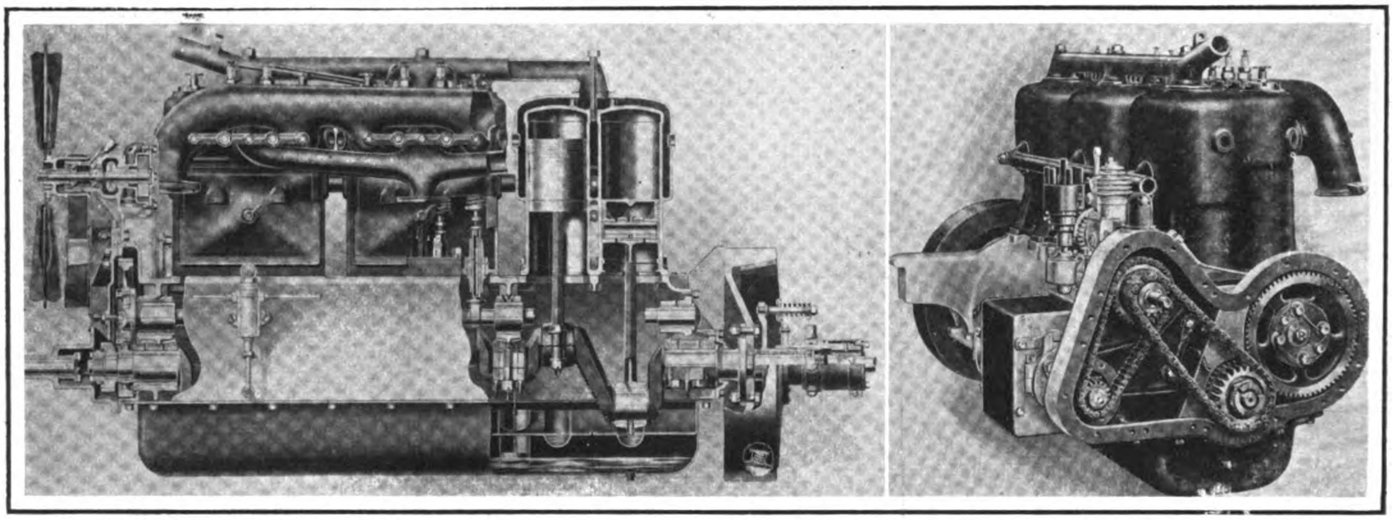
Right—One-ton freight truck moving goods from a freight car to the delivery platform



One-ton truck laying curb stone. The stones are picked up by the crane, carried to the trench in which the curb is laid and carefully lowered in place. With this device more curb can be laid with less men

Two applications of the electric to municipal work. At the left is a one-ton machine used in road making and at the right a street sprinkler. The crane on the former may be used for laying curbing or flagging, installing fire hydrants, etc.

Mitchell Adds Six Selling for $1,585



Left—Part section of new Mitchell six motor. Note exhaust carried forward. Right—Another view, with timing gear cover removed

Accessibility a Feature—L-Head Motor 4 by 5.5 Inches Used—Three Body Styles Offered

A NEW six at $1,585 has been brought out by the Mitchell-Lewis Motor Co., Racine, Wis. It has an L-head motor with cylinders 4 by 5.5 inches and is made in two, five and six-passenger body-styles. The wheelbase is 128 inches and 36 by 4 tires with demountable rims are used.

In addition to this model, the Mitchell company will continue the four-cylinder car at $1,250, the special six at $1,895 and the de luxe six at $2,350 which constitute the remainder of the line.

Several new features are found on the new six. The water pump is mounted behind the fan and is driven from the fan spindle. Adjustable inclosed silent chains are employed to drive the motor generator and ignition shafts. A power tire pump is standard equipment, being operated through sliding gears from the ignition shaft. More uniform cooling and great accessibility are obtained by reversing the position of the exhaust manifold so that the gases leave at the front end instead of at the rear. It is stated that the extensive use of chrome-vanadium steel and steel stampings have been big factors in reducing weight and at the same time increasing the strength and economy of this car.

Accessibility a Feature

Accessibility has been made a feature, it is stated, it being possible to remove the whole power plant and gearshift without disturbing the body. Each unit and portions thereof can be lifted out without touching adjacent units.

The motor of the new six has the cylinders cast in pairs. The crankcase is a barrel type aluminum casting having a removable lower cover of pressed steel which forms the splash basins and oil reservoir of the circulating oil system.

The crankshaft which is offset 1 inch from the center of the cylinders is mounted on four babbitt bearings 2.12 inches in diameter. The front one is 3 inches long, the two center ones 2.25 inches and the rear one 3.5 inches. Connecting-rods are I-beam sections having 2.12 by 2.25-inch babbitt bearings on the crankshaft. The piston pins are 1.12 inches in diameter and 1.813 inches long, are bushed with bronze, and are hollow. They are prevented from turning by Woodruff keys and brass disks separate the ends from the cylinder walls. Ground cast iron pistons are employed each having three rings with staggered joints. Small holes are drilled through the machined oil grooves around the pistons to allow the surplus oil to drain back into the crank chamber instead of working up into the combustion chamber.

Chrome nickel steel valves 1.93 inches in diameter and with 45-degree bevel seats are used. The inlet valves have .3125-inch lift and the exhaust .375-inch lift. The push rods have mushroom ends and adjustable tops.

The camshaft is a one-piece drop-forging It is driven from the crankshaft by helical gears. The four bearings have the following dimensions: Front, 2.56 by 2.03; two center, 1.75 by 2.03; rear, 2.436 by 1.25.

Lubrication of the motor is by means of a circulating splash system in which a plunger pump mounted at the right of the motor in an accessible position and driven by an eccentric on the camshaft draws oil from the base of the motor and distributes it through two leads through the engine gearcase and sight on the dash to the troughs and splash basins.

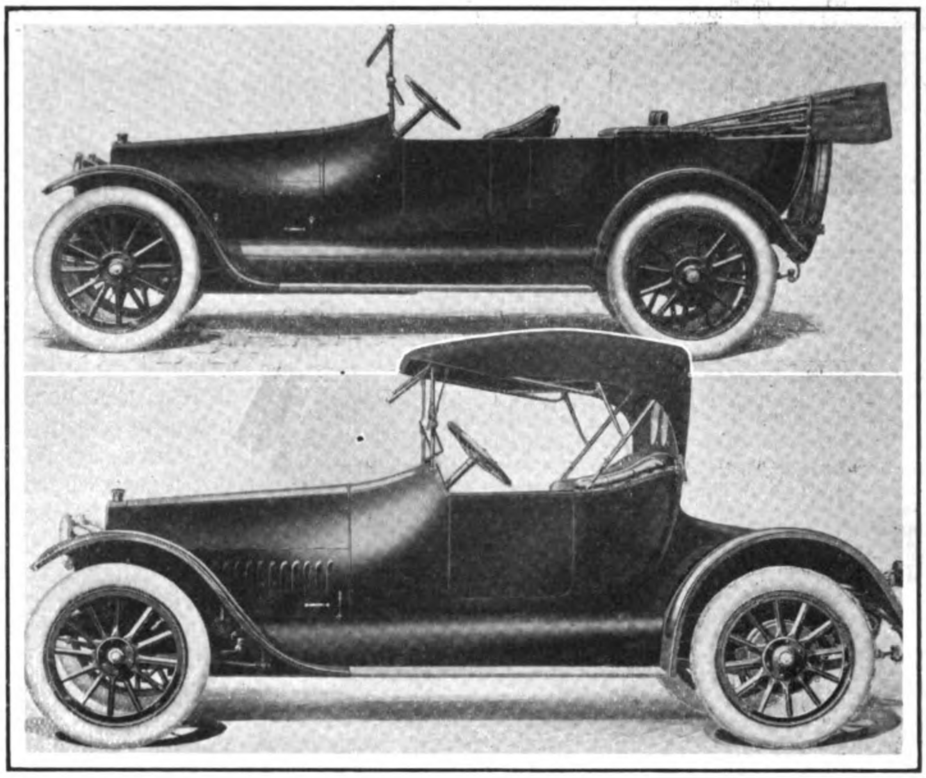
The overflow from these basins returns to the reservoir in the base of the motor. There is a float indicator on the side of the crankcase to show the amount of oil and nearby is the oil filler.

A feature of this system is that a separate lead with an adjustable feed valve branches off from the main return lead from the sight feed on the dash and conducts oil to the clutch bearing. Another feature is the arrangement of the breather openings in the valve spring compartments, thus lubricating the valve mechanism.

New Cooling Features

Several new details are noted in the cooling system. As previously pointed out, the centrifugal pump is mounted on the fanshaft where it is accessible and, should the fan belt break, the circulation would be maintained automatically, as the system is designed to operate on the thermo-syphon system in such event. Better cooling is said to be obtained by carrying the exhaust pipe forward, producing more uniform cooling of the different cylinders. In addition it prevents the undue heating of the floorboards. The radiator has a removable shell which is built entirely separate from the radiator, which makes it possible to give the removable shell three coats of oven-baked enamel, thus insuring a durable finish. The radiator is mounted on flexible brackets.

Ignition is by means of a high-tension breaker and distributer system of Continental make in which the battery furnishes the current until the electric generator cuts into operation and supplies current. Starting and lighting are accomplished by means of a single unit motor-generator mounted on the right side of the crankcase at the front. It is a Splitdorf-Apple 12-volt design. The battery is suspended inside the frame under the rear floorboards. The head lights are wired so as to be operated in series or parallel, the former giving dimmed lights for city driving.



Above—Six-passenger touring body on new Mitchell six chassis
Lower—Two-passenger roadster

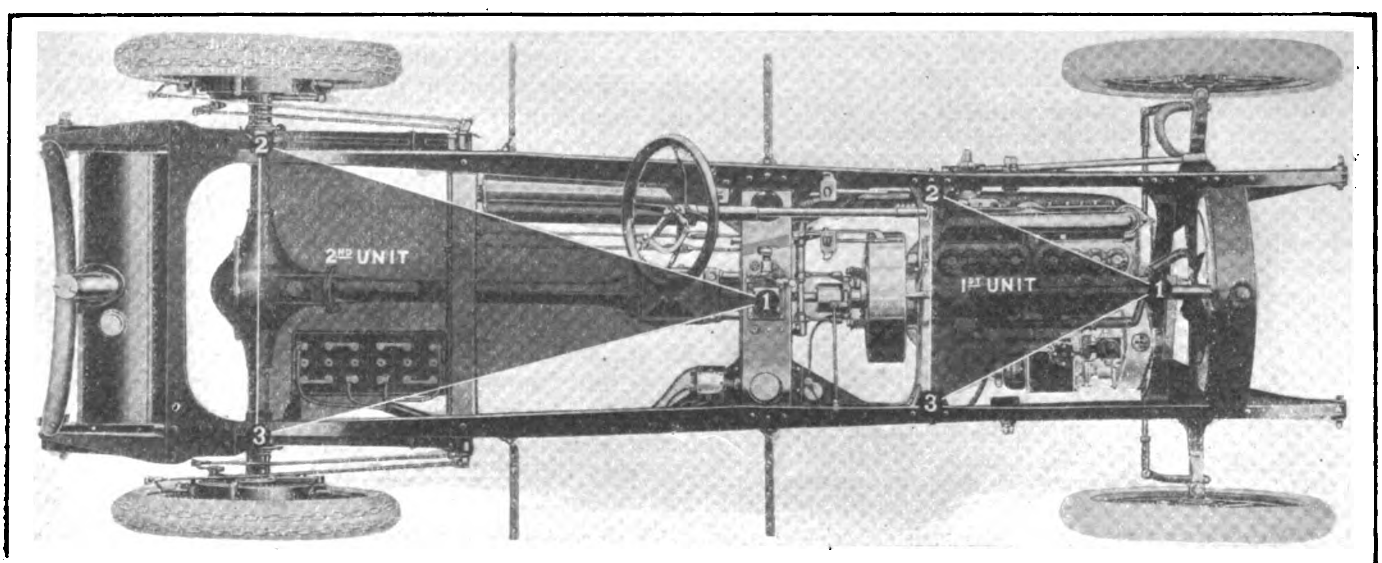
A special Rayfield carbureter is employed which may be easily primed or adjusted from the driver's seat. Fuel feed is by means of the Stewart-Warner vacuum gravity system from an 18-gallon tank mounted at the rear of the chassis. A gasoline gauge is fitted.

The clutch is a pressed steel cone, faced with leather and provided with springs to give an easy engagement.

The gearset is located at the front of the torsion tube thus dividing the power plant into two units, one the motor and clutch and the other the gearset and rear axle. The gearset is a sliding gear selective type having three speeds forward and one reverse. The gearbox is mounted at the front end of the torsion tube and is supported by a trunnion from the cross member of the frame. The countershaft is placed below the mainshaft which is squared to carry the sliding gears. Single and double row annular ball bearings and roller bearings are employed in the gearbox. The gears are made of chrome-vanadium steel and have 1-inch faces.

The driveshaft is bolted to both the gearset and rear axle housing. The axle is floating and accessible through a large cover plate at the back of the housing. The pinion is mounted on a double-row ball bearing in front and a double one behind, and has ball thrust bearings as well. The bevel gear and differential unit is mounted on roller bearings provided with a ball thrust. Driveshafts have splined ends and are easily removable. A standard gear ratio of 4 to 1 is furnished, but there are several others to order. The brakes act on 14-inch drums on the rear wheels, the pedal operating the external set and the lever the internal. The bands are lined with a non-burnable asbestos fabric, and conveniently located turnbuckles are provided to facilitate adjustment.

Three-quarter elliptic springs 2.25 inches wide and 50 inches long are used in the rear and the front springs are flat, half-elliptics 2 inches wide and 40 inches long. Steering is by means of an irreversible worm and gear.



Mitchell four chassis, showing three-point suspended double unit construction used in new six

Truck Trash?

IN no more euphonious terms than "truck trash" are some English makers and publications designating much of the truck purchases made in America by some of the Allies.

England, or any other country, has got incorrect information on much of the American buying. One ally sent her representatives here and today has purchased over 2,500 trucks from reputable makers which cannot be considered trash, neither can any of these makers be considered as getting rid of products, rather, they are manufacturing their best goods for the foreign trade. They are testing them out perhaps a little better than might be done for home use, due solely to the extreme service in view.

It is certain that if foreigners form their conceptions of American trucks from the opinions expressed by many of the hordes of so-called brokers at present infesting our cities and looking for large middle-man profits there might be some possibility of some trash finding its way to the other side. But neither the Germans and Austrians, nor the Allies require to do business through such sources. Our truck makers are big enough to do business direct. All of the belligerent countries can feel safe in sending their emissaries direct to our factories. Our factories will stand inspection, the materials will stand analyses, the workmanship will stand the micrometer, in fact, they will find honestly made articles and not trash.

Patent Reciprocity

LAST week's action of the members of the National Automobile Chamber of Commerce, Inc., in which over half agreed to grant privileges on the patents they hold to others in the chamber holding patents and also granting reciprocal privileges, should go a long way toward limiting wholesale patent litigation, which is such a destructive force in any growing industry.

This new system, cross-licensing, is really patent reciprocity among those makers who control patents relating to automobile construction. There are over ninety members in this one association, and if all agree to patent reciprocity, it will at least assure for 10 years, the period of the agreement, that the patent legal mill will not be working so consistently on an over-time schedule as has been the case in the past.

No other agreement could better indicate the high spirit pervading the American automobile field, than this reciprocity one. It is how business men should get together. It is in harmony with the petitions presented before the Inter-State committee a year or so ago, when the automobile makers asked for a "peace policy," a time when they would be free to pursue the course of manufacture and merchandise, in contrast to a period when they would be irritated with the over-hanging cloud of over-legislation. The present act is a commendable step in the direction of eliminating an over-crop of automobile patent litigation.

This patent reciprocity is in line with the dominant thought with many automobile makers that they want patents as means of protection against those, who securing patents, might demand tribute from others who might have had a prior right to the patents. There is no thought in the present reciprocity program of diminishing the intrinsic value of a patent, there is not any thought of trying to reduce the value of a patent to the inventor, rather that patents will continue to be applied for and used as in the past, but that the individual automobile companies will use these patents for personal protection, against those who might demand tribute from the entire industry for their privileges.

It is estimated that at present there are over 900 patents controlled by those automobile makers, who are members of the present chamber, and under the proposed régime, the reciprocal use of these, or some of them, will be shared only by those companies that agree to pool their patents in this reciprocal scheme. Such a pooling of mutual interests should go a long way toward better protection for the makers so concerned, and it should result in a very considerable reduction in expenditures on patent litigation. In the last 2 decades there are examples of industries that have sapped much of their life blood by patent matters, and if this can be avoided it would seem a rational undertaking to avoid such. The working out of the present reciprocity scheme will be watched with more than ordinary interest, not only in the automobile field, but in other industries that have been long disturbed by the legal difficulties connected with patent suits.

Makers Cannot Maintain Prices Through Contracts with Dealers

Cincinnati Court Holds That License Contracts Involved Are Not of a Form Approved by Supreme Court

CINCINNATI, O., Dec. 8—Manufacturers' efforts to enforce price maintenance on their cars by means of contracts with their dealers are futile, according to the decision of the United States District court in Cincinnati, O. Judge Hollister of this court last week dismissed a bill of complaint brought by the Ford Motor Co., against the Union Motor Sales Co., Dayton, O., the basis of which was price-cutting.

The Union Motor Sales Co. is in a way a co-operative organization; customers are supposed to be stockholders, taking a $10 share of stock before sharing in the benefits of the company; goods were advertised at less than regular prices, and one of the favored items had been Ford cars.

Ford had declined to sell this company cars and in the suit which was brought about a year and a half ago charged that the Union Motor Sales Co. had conspired to obtain cars from regular Ford dealers, which cars were sold at less than list; this suit asked $50,000 damages and an injunction restraining the Motor Sales from selling any more Fords. A preliminary injunction was granted July 1, 1912.

A year later Ford charged Lucien A. Howard and O. D. Noble, of the Motor Sales, with contempt of court in continuing the forbidden practices; the charge was sustained in court. But within the past year or so there have been numerous high court opinions on price maintenance and these undoubtedly had much to do with Judge Hollister's ruling. He dismissed the Ford suit in its entirety.

Contracts Held Invalid

In the trial of the action it was proved that the Motor Sales had secured Fords and sold them to stock members at from 10 to 15 per cent. less than list. The Ford contracts, however, were declared invalid by Judge Hollister, whose opinion covers fourteen typewritten pages. He declared that the license contracts involved are not of a form approved by the United States Supreme Court. The Ford company's licenses are in connection with patents on its cars.

"The rights of the parties," ruled the court, "depend upon the construction to be given the written contracts entered into between the Ford Motor Co. and its so-called 'dealer licensees,' and so far no case involving a contract precisely like the agreement between the complainant and the dealers who sell cars made by it and covered by its patents has been presented to the Supreme Court.

"An agreement by the patentee, giving to another the rights to manufacture under the patent and to sell at a fixed price on a small royalty has been held not to come within the jurisdiction of the Sherman anti-trust act. (Bement vs. Harrow Co.)

"It is conceded that contracts such as made by the complainant with its dealers would, were it not for the fact that the article sold was made by the complainant under its patents, be contrary to public policy under the decisions in Dr. Miles Chemical Co. vs. Parke. But it is claimed that since the complainant does manufacture its cars under its own patents it has the right to maintain a monopoly of the exclusive right to sell, granted by the patent law, by a contract of sale with its dealers, fixing the price on resale at which the dealers may sell to the user, although by so doing the competition between the dealers is thereby effectually prevented.

"There is, however, a marked difference between these contracts and the license contracts to which the Supreme Court has given its approval. For, in this case, the patentee is the maker and does not, in terms at least, receive a royalty, but actually sells each machine at a price fixed by itself and is paid by the dealer all that the maker asks for the article sold. There is no question of restricted use in this case as in that of Henry vs. Dick, for the contract is either a complete sale of the exclusive right to sell given the complainant under the patent laws, or a license to sell, which involves a reservation of some part of the exclusive right to sell, or, as contradistinguished from these, amounts to a sale.

"For the purpose of this case it may be assumed that if the contract partakes of the quality of a sale of the exclusive right to sell, or of a license to sell, it is a good contract which the complainant may legally enter into with its dealers and, under the facts proved in this case, an injunction must be issued against the defendants.

"But if, under the terms of the contract, the complainant has sold the automobile made by it and delivered the sale to its dealers, passing the title upon the receipt of the contract price, then, under the decisions of the Supreme Court, and on principle, the conclusion in my judgment must be that by such sale the complainant * * * cannot legally fix the price at which the dealer shall re-sell. The contract does not deal with the use of the automobile sold; hence, to call it a contract for 'restricted sale' is a misnomer, and the adoption of such a definition is, as said by Mr. Justice Day, 'a mere play upon words' (Bauer vs. O'Donnell)." The latter is the famous Sanatogen case.

Besides the Union Motor Sales Co. the defendants were: Lucien A. Howard, J. Carl Horton, Early S. Sorsley and William T. S. Yokum, all of Dayton.

Horn Patent Litigation Draws to Close

NEW YORK CITY, Dec. 5—The order extending the term of the court for all purposes of the suit of the Lovell-McConnell Mfg. Co. against the Automobile Supply Mfg. Co. for 6 months from the date of the final decree was vacated yesterday by a memorandum issued by Judge Veeder.

It was brought out in the memorandum that, while an extension of the term was not required for the assertion of any rights remaining to the Lovell-McConnell company, the publicity given to the order had injuriously affected the Automobile Supply Mfg. Co. This suit is now at an end, unless the Klaxon makers petition for a hearing before the Supreme Court of the United States. The order in question was granted by Judge Chatfield October 31 on motion of the Klaxon counsel following the confirmation by the Circuit Court of Appeals of the decision of Judge Coxe handed down on June 8 in favor of the Automobile Supply Mfg. Co.

The memorandum was issued in the United States District Court for the Eastern District of New York.

Savage Motor Officials Freed of Fraud Charge

CINCINNATI, O., Dec. 7—The trial of Delbert H. Cummings, Robert W. Fishback and Edwin E. Taylor, president, vice-president and secretary respectively of the Savage Motor Co., charged with using the mails in a scheme to defraud was brought to an abrupt close in the United States court at Cincinnati last week when Judge Hollister ordered the jury to bring in a verdict for the defendants. He held that there was not sufficient evidence adduced showing an intent to defraud. The three men had received on an average about $200 in deposit each from about 300 agencies to handle the Savage 20 which was never placed on the market. The defendants claimed that it was because of their arrest that they were unable to place the car on the market.

DETROIT, MICH., Dec. 8—Henry B. Joy, president of the Packard Motor Car Co. and director of the Federal Reserve Bank, Chicago District, is convalescing in Roosevelt Hospital, this city, after having undergone a minor operation.

Mr. Joy recently sustained a bump on his head while on a test trip with an experimental car, resulting in a painful bruise. It was found several days later, after other symptoms had developed, that a slight surgical treatment was necessary. Reports indicate that the Packard executive will be discharged from the hospital within a very short period.

N. A. C. C. Recommends Interchange of Patent Licenses by Makers

Reciprocal Agreement Urged to Prevent Litigation Over the 900 Patents Owned by Members — Chamber Votes to Defend Axle Patent Suit

NEW YORK CITY, Dec. 5—Yesterday, at an important meeting held by the National Automobile Chamber of Commerce, the members showed the united condition of the automobile industry by recommending for general adoption by the industry a cross-licensing agreement which provides for makers to interchange licenses on patents which they own.

This interchange or cross-licensing system, which was signed by practically one-half of the companies present, is one of the most important steps taken by the chamber since its organization. There are now over 900 patents owned by the members, and by this cross-license scheme each maker grants the permission to use his patents to every other maker who reciprocates. The agreement takes effect January 1 and is for a 10-year period. The object of the cross-licensing system is to avoid patent litigation among members, who have patents taken out more for protective measures than for the purpose of securing revenue from them.

To Defend Axle Patent Suit

At the same session the members voted to take over the defense of the suit on rear axle patents brought by the Kardo Co. against the Studebaker Corp. in Chicago, as reported in THE AUTOMOBILE for November 19. It is stated that the members of the Chamber will follow the same course in the event of any other similar suits being brought against companies belonging to the organization.

Henry B. Joy, president of the Packard company, read a letter he had addressed to E. R. Benson of the Studebaker Corp., which was more or less in explanation of the Kardo litigation against the Studebaker company, which litigation was the real cause of the meeting. The latter was largely a reply to a circular distributed among the Chamber members and in which the statement had been made that the Kardo company was really organized to exact tribute by way of patent royalties from the industry. Mr. Joy refuted this and stated that if ninety-three of the largest automobile manufacturers are to band themselves together for the purpose of ignoring the rights of inventors that inventors should really seek the patent courts. Mr. Joy referred to the meeting of the Chamber on May 6, in which it outlined the policy of patent peace and referred to the present action as a complete change of direction in this matter. He said that the Kardo company soon after the May meeting sent to every member of the Chamber a list of Packard patents with an expressed willingness to grant licenses under any and all of them under reasonable terms, and that the company was ready and willing at all times to accord others exactly the same recognition of their patents that he asked for those of his company.

In regard to the recommendation for a cross-licensing agreement on patents, the thought was expressed that the industry has prospered by scientific manufacturing of a product of excellent quality, and that, while each company held some patents of great value, it would be better for the industry at large that each concern, while developing its own ideas and standards with the idea of building the best possible machines, should be free from attack on patents owned by the others. As General Manager Alfred Reeves of the Chamber expressed it, the whole thing resolved itself down to the question whether one maker's patents are more important than the entire balance of the industry. An idea of the disastrous possibilities in the way of patent litigation which are possible may be gained from the fact that members of the Chamber own between 900 and 1,000 patents and that there are at least six or seven important patents on each part used in car construction. Naturally, when the cross-licensing idea was proposed, there was an animated discussion although this was all along the same lines.

Trade Conditions Favorable

The discussion of general trade showed that the industry, aided by the favorable weather conditions and returning business prosperity, has more than held its own, even during the fall months. Export trade has suffered considerable, so far as passenger cars are concerned, on account of the war, although this is offset to a large degree by the sale of motor trucks to foreign countries.

President Clifton presided over the meeting at which were represented practically all the leading automobile manufacturers, as indicated by the accompanying list.

Aluminum and Petroleum Show Big Gains

NEW YORK CITY, Dec. 8—The Department of Commerce, Washington, D. C., has issued a statistical record of the progress of the United States from 1800 to 1914 and also the monetary, commercial, and financial statistics of the principal countries.

A number of the principal commodities show a remarkable growth, for instance, aluminum, whose production rose from the modest figure of 83 pounds in 1883 to 65,607,000 in 1912,

the latest estimate. This metal, which was first manufactured commercially in 1889, showed a production that year of 47,468 pounds. In 2 years it jumped to 150,000 and in 1896, went over the million mark, the exact figures being 1,300,000. In 1906, the production reached 14,910,000 pounds, and that mark was practically doubled in 2 more years, the figures being 34,210,000.

Petroleum also showed a large increase. In 1859, the first year it was used in this country for commercial purposes, 84,000 gallons were produced. This product immediately showed signs of a tremendous production, the next year's production being 21,000,000 gallons. In 1862 the production jumped to 128,380,980 gallons. In addition to this amount it is estimated that 10,000,000 barrels ran to waste in and prior to that year. The next 3 years showed a decrease, after which the production picked up and a gradual increase occurred up to 1875, when the production was 510,825,588 gallons. This included all the production prior to 1876 in Ohio, West Virginia, and California. The 2,000,000,000-gallon mark was reached in 1891, the exact figures being 2,280,291,510. From then on the increase was steady, the latest figures being in 1913 with a production of 10,434,741,660 gallons.

N. Y. Garagemen Confer on Fire Regulations

NEW YORK CITY, Dec. 9—The Automobile Trade Assn. of New York State has compiled data as to the effect if the temporarily suspended rules of State Fire Marshal John F. Ahearn were enforced and will meet that official today in Albany, prepared to help revise the regulations so that the drastic features will be eliminated. It will be proposed that certain sections be struck out and that others be altered.

The association sent to garagemen a question blank, asking what the enforcement of the rules would mean. The replies indicate that it would cost more to remodel existing buildings in accordance with the rules than it would to build new structures; the cost in many cases was from $10,000 to $15,000.

This morning, Wednesday, December 9, the Board of Directors of the association will meet in Albany and will discuss plans for the meeting with the fire marshal in the afternoon. Besides the directors the conference will be attended by President R. H. Johnston, Secretary Charles A. Stewart and Attorney Charles Thaddeus Terry.

Boston Dealers Continue Separator Fight

BOSTON, MASS., Dec. 5—Next week it is expected that the matter of whether or not all the garages and service stations of the motor dealers in what is termed Metropolitan Boston, which embraces Boston and surrounding cities and towns within an area of about 15 miles, will have to install separators at a cost of several hundred dollars each. It would not be surprising if Fire Hazard Commissioner John A. O'Keefe, who has the last say in the matter, would compromise with the motor organizations and frame rules guaranteed to prevent danger without the necessity of every one installing a separator. If that is done it will be the result of energetic, intelligent action on the part of the officers of the automobile organizations, who have been working on the matter.

Chester I. Campbell of the Boston Automobile Dealers' Assn. has prepared a series of questions which have been printed on blanks that will be circulated to all garages in the city. These questions aim at securing complete information relative to Boston garages, gasoline storage systems, pumps, etc., and should assist in reaching a definite conclusion regarding whether separators are necessary or not.

New York Men Form State Federation

NEW YORK CITY, Dec. 8—There is being organized today in Syracuse, N. Y., the New York State Federation, an organization of motorists, which is breaking away from the New York State Automobile Assn., the state body federated with the American Automobile Assn. The new organization is a result of opposition to the older organization and it is expected that the three big motor organizations of the state, namely, clubs from Buffalo, Rochester, Syracuse and the Metropolitan Consulate of this city will combine in the new organization, giving a total membership of approximately 10,000. With this loss the old organization will have approximately 6,000 remaining members. The new Federation will affiliate itself with the A. A. A. by its clubs joining individually.

California Has New H.P. Formula

State Officials Devise Way to Raise Its Long-Stroke Motor Fees for 1915—A War Tax

LOS ANGELES, CAL., Dec. 3—P. F. Meckes of the Los Angeles branch of the California State Motor Vehicle Dept., returned from Sacramento yesterday afternoon with the formula that is to be used next year for determining horsepower on motors to be taxed in this state. The formula is: Bore + stroke × bore × number of cylinders × .224.

The owner of a long-stroke motor pays from $5 to $10 more under this system. Local dealers and prominent motorists are greatly opposed to the new formula and there is a lot of talk about taking the matter to court to get a decision on what is a horsepower.

It is argued that either the State of California was flimflammed out of $150,000 last year, or the motorists are to lose that amount this season.

War Tax for Car Owners

NEW YORK CITY, Dec. 4—Automobile owners and applicants for chauffeurs' licenses must help pay the new revenue tax, J. A. Parsons, Attorney General, decided today. The Secretary of State was uncertain as to the application of the new law to his office, and asked Mr. Parsons for a ruling.

The tax will be 10 cents more for the 1915 privileges than was paid last year. There are 166,961 automobiles registered and about 75,000 chauffeurs; this will give the Government about $25,000. This is in pursuance of the stamp tax law passed by Congress, October 22.

Every applicant must send with his application a 10-cent revenue stamp, left loose for affixing by the office issuing the papers.

Over in New Jersey Commissioner of Motor Vehicles J. H. Lippincott, acting under an opinion of Attorney-General Westcott, announced recently that war revenue stamps were required on the application for license cards.

The special taxes are as follows:

Car registration certificate, 10 cents; motorcycle registration certificate, 10 cents; driver's license certificate, 10 cents; learner's permit certificate, 10 cents; all duplicates and transfers, 10 cents; power of attorney for non-residents, 25 cents and affidavit on application, 10 cents.

The State of Maryland is also demanding from each applicant for registration a tax of 10 cents. This went into effect December 1. Each application must bear a 10-cent stamp hereafter.

Pennsylvanians Want State Road Tax

PHILADELPHIA, PA., Dec. 4—At a special meeting called yesterday to consider prospective new legislation at Harrisburg of interest to automobilists, various methods of providing for early improvement of Pennsylvania's roads were discussed by the Executive Committee of the Pennsylvania Motor Federation at the Automobile Club of Philadelphia.

After several speakers had been heard, ex-State Senator Adams, chairman of the legislative committee, was instructed to draft a bill at the coming session of the state legislature providing for the levying of a special state road tax on all taxables, individual and corporation, who now pay a state tax, and including real estate that pays no state tax.

States Want Uniform Traffic Regulations

NEW YORK CITY, Dec. 7—Conferences recently held in this city and Trenton, N. J., by representatives from this state, New Jersey, Pennsylvania, Maryland, Delaware, the District of Columbia and the New England States, point towards the adoption in the near future of uniform traffic regulations there.

A commission has been appointed in New Jersey by Governor Fielder composed of J. H. Lippincott, commissioner of motor vehicles, chairman; A. V. Hamburg, president of the Newark board of trade, and G. B. LaBarre, director of public safety of Trenton.

October Exports Total $3,055,351

672 Trucks and 732 Passenger Cars Are Shipped—Trucks Gain 593 Machines Over 1913

WASHINGTON, D. C., Dec. 8—The large demand for commercial cars as a result of the European war is shown in the October exports, made public today by the Federal Bureau of Statistics. In that month 672 commercial cars, valued at $2,286,964, and 732 pleasure cars, valued at $768,387, were exported, as against seventy-nine commercial cars, valued at $129,506 and 1,697 pleasure cars valued at $1,663,716, exported in the same month last year. The exports for the 10 months ended October last were, 1,309 commercial cars valued at $3,353,509 and 20,262 pleasure cars, valued at $17,888,351.

P. O. Dept. Bids for Tires Dec. 16

WASHINGTON, D. C., Dec. 8—The Postoffice Dept. will open bids on December 16 for furnishing pneumatic, solid or cushion tires for the postoffice motor cars. Information for the bidders will be furnished by the purchasing agent of the department, this city.

WASHINGTON, D. C., Dec. 8—The Duplex Power Co., Charlotte, Mich., has been awarded a contract to furnish the Quartermaster Dept. of the War Dept., two four-wheel-drive trucks.

LIMA, O., Dec. 8—The Gramm-Bernstein Co., Lima, O., has booked an order for twenty-five trucks to be used by the departments of the Federal Government at Washington, D. C.

Two $1,900 Worm-Driven Federal Trucks

DETROIT, MICH., Dec. 5—The Federal Motor Truck Co., which thus far has made only chain-driven trucks, is now placing on the market two worm-driven models, both of 1 1-2 ton capacity.

Both models sell at $1,900 and while model J has a wheelbase of 120 inches, Model K's wheelbase is 144 inches. Both have a Continental motor, 4 1-8 by 5 1-4. The sizes of the tires are 36 by 3 1-2 on the front wheels and 36 by 5 on the rear wheels, or dual tires.

$725 Crow with Electric Starting and Lighting

ELKHART, IND., Dec. 8—The Crow Motor Car Co., Elkhart, Ind., has made public the first details of a new five-passenger model which is to sell for $725 with electric lighting and starting and otherwise fully equipped. It is fitted with a 25-28 horsepower block motor, supported at three points, a multiple disk clutch, a four-speed selective gearset and a full floating axle. The body conforms to the modern streamline principles and is built on a wheelbase of 104 inches. The gasoline tank is in the cowl and the spring suspension includes the usual semi-elliptic front members with underslung three-quarter elliptics in the rear. The equipment includes electric horn, top, windshield, Stewart speedometer and oversize tires.

Waverley Shop Trucks for Government

INDIANAPOLIS, IND., Dec. 8—The Waverley company of Indianapolis has under construction for the Navy Yard on Puget Sound, Washington, a 3-ton electric shop truck with 3-ton trailer for handling plates and angles from storage to machines and from machine to machine through the Naval Repair Shop.

The tractor is of unusual design in that with a wheelbase of 66 inches the platform of the car is 5 by 11 feet, the principal overhang being in front of the front axle.

The battery of forty-two cells is divided between two battery boxes, one between the wheels and the other under the forward overhang.

Mounted on the platform of each car is a turntable 5 feet 2 inches in diameter running on rollers and operated by hand spikes for the quick and convenient unloading of the heavy plates or beams it is designed to carry.

The construction of both cars is very substantial, wheels axles, frames, turntables and all being of heavy steel. A single motor is used and the power is transmitted to the rear axle by means of a worm-gear-shaft drive.

A mileage of 30 miles on a single charge of the battery is provided and a speed of 5 1-2 miles an hour with both cars fully loaded.

Storms Electric Leases Mercury Plant

DETROIT, MICH., Dec. 5—The Storms Electric Car Co., which was organized last week, has leased the plant formerly occupied by the Mercury Cyclecar Co., 807 Scotten avenue. This is a two-story structure having about 25,000 square feet of floorspace. The first models of the Storms electrics are now being completed and will be shown at the Detroit automobile show, in January.

N. Y. Stock Exchange Opens Dec. 12

NEW YORK CITY, Dec. 8—The New York Stock Exchange will open Saturday, December 12. The Governors have voted to permit restricted trading in stocks on the floor of the Exchange starting that day, after being closed 19 weeks, since July 30.

Approximately 175 stocks will be traded in cash or regular way only. Dealings in stocks as such shall be specified by, and be under the supervision and regulation of, the committee of five, shall be for cash or regular way only and not below the minimum prices authorized by the committee from time to time. Transactions at prices below those allowed by the committee, or in evasion of its rules, are prohibited.

Automobile Securities Quotations

NEW YORK CITY, Dec. 8—A general strengthening of the automobile security market was perceptible during the past week. Kelly-Springfield Tire established a new high record and several other stocks showed substantial gains. The following bid and asked quotations are those which a prominent brokerage house finds to obtain in private sales and are to be taken only as a guide until the reopening of the Stock Exchange.

Goodyear Profits $3,391,165 for Year

$1,183,418 Is Reserved for Depreciation—Unappropriated Surplus of $4,052,395 Remaining

AKRON, O., Dec. 8—The Goodyear Tire & Rubber Co.'s net income for the year amounted to $3,391,165. Additional credits not applicable to the operations for the current year amounted to $38,062. Additional debits not applicable to the current earnings amounted to $154,560. There remains an unappropriated surplus of $4,052,395.

F. A. Seiberling, president of the Goodyear company, in his remarks to the stockholders at their annual meeting says:

"Increases to the plant have been carefully received. The reserve for depreciation amounting to $1,183,418 is equivalent to 18.63 per cent. of the plant value of $6,351,250 as of October 31, 1913. The inventory was taken by the company by actual count, weight or measurement under the supervision of the company's factory superintendent and has been certified by him. It is priced at cost or under including crude rubber, which latter commodity is priced both under cost and under the present market value."

In 1913 the company did a gross business amounting to $32,500,000, an increase of $7,000,000 over 1912. The net profits were $2,041,000, equal to 33 per cent. on the common stock.

During 1914, by charter amendment the authorized preferred capital stock was increased from $5,000,000 to $7,000,000 and the common capital stock reduced from $10,000,000 to $7,991,110. In 1913 the company had outstanding $5,000,000 preferred and $5,033,800 common. The balance sheet as of October 31, 1913, shows a reserve for accounts and depreciation of $1,367,390, and a surplus of $2,820,071. The company during 1913 built large additions to its factory costing $2,495,680.

The balance sheet as of Oct. 31 last compares as follows:

Assets	1914	1913
Real estate and buildings	$3,606,537	$3,493,535
Machinery and fixtures	3,208,107	2,857,714

Reserve for depreciation of plant	1,183,418	858,909
Surplus	4,052,395	2,820,071
Total	$21,459,335	$18,858,251

Studebaker 1914 Profits Estimated Double 1913

NEW YORK CITY, Dec. 7—Net profits of the Studebaker Corp. for 1914 will be more than twice as great as in 1913, according to information. On the basis of actual figures for the 9 months ending September 30, it is estimated the profits, after depreciation and interest charges, will be about $4,000,000, comparing with $1,904,823 last year. Accordingly the surplus available for dividends on the common stock would be equal to 11 per cent. on the $27,931,600 stock outstanding.

Since January 1 the company's serial notes outstanding have been reduced from $6,800,000 to $5,800,000. In addition to the $800,000 that matured, the company cancelled $200,000 bought in the open market.

E. H. Huxley Heads U. S. Rubber Export Co.

NEW YORK CITY, Dec. 4—Organization of the United States Rubber Export Co., Ltd., incorporated last week with a capital of $100,000 under the laws of Delaware, was completed yesterday by the election of these directors: S. P. Colt, president of the U. S. Rubber Co.; Lester Leland and J. B. Ford, vice-presidents of the same concern; E. S. Williams, president of the Rubber Goods Mfg. Co.; H. E. Sawyer, general manager of the United States Rubber Co.; R. B. Rice, C. C. Case, W. E. Barker, J. C. Weston, E. H. Huxley, H. S. Hotchkiss and W. J. Maloney.

These directors elected the following officers: President, E. H. Huxley; treasurer, W. C. Parson; assistant treasurer, H. S. Hotchkiss, and secretary, J. D. Carberry. The new export company has been organized for the purpose of consolidating the export business of the United States Rubber Co. and its associate companies.

Indianapolis to List Used Car Sales

INDIANAPOLIS, IND., Dec. 8—If an ordinance which the Indianapolis council has under consideration becomes effective, dealers in used cars, parts and accessories will be required to list all purchases with the police department. The ordinance contemplates detailed reports which must be made out within 24 hours after every purchase. A heavy fine, to which a jail sentence may be added, is provided for conviction for violations.

NEWARK, O., Dec. 8—The board of trade of Newark, O., at a recent meeting pledged both moral and financial support to the Blair Motor Truck Co., which was recently organized to manufacture motor buses. A committee of five was named to confer with the officials of the company with reference to its needs. It was stated that about $60,000 additional capital was needed to take care of orders which have been booked.

Market Reports for the Week

Market reports this week remained generally unchanged. There were a few unimportant changes such as the drop of $0.25 per 100 pounds for tin, the slight decline of both coppers, the rise of rapeseed oil to $0.72, rubber closing at $0.71 at a gain of $0.01 and the raw Japanese silk gain of $0.02. The sales in tin were few with very little demand for either spot or future positions. The demand for copper was light and selling interests were more anxious to make sales, especially for nearby delivery. Even late futures were weaker in tone. In Europe apparently prices of electrolytic were nominally unchanged, but slightly easier in tone. Antimony is steady for spot and firmer for future delivery. Lead remained quiet but steady. Cottonseed oil, which went up $0.22 per barrel held a better tone this week with an improved consuming demand. There was absence of new developments of importance in the crude rubber market. Though there was a gain of $0.01, prices were generally steady. The demand from manufacturers was reported as light. In discussing the embargo placed by England on shipments of plantation rubber a large manufacturer of tires states that two ships bearing crude rubber reached this country during the last few days, and that there is only one other ship bearing rubber on the high seas bound for the United States. This ship left Singapore before the establishment of the embargo.

Race Dates for 1915

Contest Board of A. A. A. Reports 120 Sanctions for 1914—Official Records Announced

NEW YORK CITY, Dec. 4—At today's meeting of the Contest Board tentative dates for 1915 speed contests were allowed as follows:

Indianapolis Speedway	May 29
Galesburg, Ill., 200-miles	June 16
Sioux City Speedway	June 25
Tacoma Road Race	July 4
Elgin Races	August 20 and 21

Applications were made for dates from the recently organized Minneapolis Speedway, also the Sheepshead Bay Speedway promoters and the Detroit speedway, but owing to construction not having started on some of these no consideration was given the dates.

The official summary of sanctions issued by the Contest Board for the present year shows a total of 120 as compared with 101 last year, 132 in 1912, 117 in 1911, and 166 in 1910. In the last 5 years 1910 stood first in the contest field, 1912 was next, followed by 1914. The two poorest years were 1911 and 1913.

A further analysis of the 120 sanctions issued this year show that fifty-two were on 1-2-mile dirt tracks, thirty-six on 1-mile dirt tracks, ten were road races, eight reliability tests, two hill-climbs, four certified trials, and one each of beach races, commercial vehicle tests. Sanctions were issued to two speedways during the year, Indianapolis and Sioux City.

Many records made on speedways and tracks for the year were allowed, these including Indianapolis speedway records up to 500 miles made on May 30. Oldfield in the Stutz gets two of these marks, namely 20 and 25 miles, and all of the others above this go to the foreign cars. Other records were granted including 15 miles, 20 miles, 25 miles, and 75 miles to Burman on 1-mile dirt tracks, and 100 miles to Alley on a dirt track.

The annual statement of the Contest Board showed total receipts of $16,777.51, as against total expenses of $10,688.10, leaving a surplus for the year of slightly over $6,000. The receipts were from five sources, namely, sanction fees, drivers' registration fees, track licenses, fines and appeals. The sanction fees totaled $13,640 and the fees from the registration of drivers, $2,257.

Following are the claims for records:

San Diego To Have $10,000 Race

LOS ANGELES, CAL., Dec. 3—The entry blanks for the San Diego Exposition Road Race which is scheduled for January 9, were distributed today. The event is to be conducted under the auspices of the Al Bahr Temple, Mystic Shrine, San Diego, under official A. A. A. Sanction No. 786. The event is to be managed by A. M. Young of this city who managed the recent Corona road race.

The San Diego event is to be run over the spectacular Point Loma course which measures 5.982 miles to the circuit. The total distance for the race is 305.082 miles or 51 laps. There is to be but one event, the Class "D" non-stock free-for-all. The entry fee is $150 and $10,000 in cash prizes is to be awarded, with an additional $2,500 for a new world's record for a distance not less than 300 miles.

While no entries have been officially announced, the management stated today that it was practically assured that all the drivers who appeared at the Corona speed meet, would drive at San Diego and later go north to compete in the Vanderbilt and Grand Prix at San Francisco in February.

Earl Cooper left for the East yesterday in company with Fred J. Wagner, but is to return in time for the San Diego meet. Bob Burman is in Los Angeles, but Ed. Rickenbacher has gone to New York for parts for the Peugeot cars which were disabled at Corona.

Harry Grant and Harry Babcock with the two Sunbeams are repairing the machine which was wrecked by fire in the Corona race and Grant stated today that he believed the car would be ready for the San Diego race.

The Duesenberg team is still here and wil lenter the next California race.

Barney Oldfield is reported to be signed to drive a Maxwell at San Diego, but the veteran driver says that he will not know what car he will drive or if he will drive at San Diego at al lor not, until the practice starts on the Point Loma course, January 2, the day after the exposition opens.

Eddie Pullen went north to look over the San Francisco course today and said it was probable that he would pilot the Mercer at San Diego, although there was nothing certain.

The Stutz trio is to be in the race and the entries are to be filed early next week, according to the race management.

Ralph De Palma has returned to the East but is to be back for the San Diego event according to close friends here.

Race Course for San Bernardino

SAN BERNARDINO, CAL., Dec. 3—A 10-mile motor race course around Perris Hill, just north of this city, is being seriously considered by San Bernardino capitalists and automobile enthusiasts. The project has been placed before the local Chamber of Commerce and the Board of Supervisors and it is probable that construction will be commenced within a short time.

The proposition is being backed by Charles Rouse and John Anderson of this city. Anderson is the local representative for the Western Automobile Assn.

Haynes Six on 100-Mile Low Gear Test

NEWARK, N. J., Dec. 5—A severe test of the ability of the Haynes light six to stand the continuous use of the low gear was made on Friday, December 4, when a demonstrating car was given an all-day low-gear run by Clarence R. Schuyler, manager of the Haynes branch in Newark, N. J. The total distance covered was 180.4 miles, of which 166.1 miles were covered without stopping the motor. A stoppage in the 15th mile due to a clogged gasoline line was the only untoward incident of the trip.

The car was driven 100 miles, non-stop, in 6 hours 52 minutes, and the distance for 10 hours running was 151.2 miles, a little better than 15 miles an hour. The consumption of gasoline for the whole 180.4 miles was 23 gallons, 7.8 miles to the gallon, and the oil used was 7 quarts, 25.7 miles per quart. No water was added to the cooling system and the car returned at the end of the run with the radiator practically as full as when starting out; the actual drop of the water level was less than a quarter of an inch. A motometer showed that the temperature did not rise higher than 160 degrees Fahr. at any time; the average was about 115 degrees. The water did not boil at any time and the water jackets were not too hot to lay the bare hand on even at the tops of the worst of the many bad hills.

The touring car used was a stock model used as a demonstrator and had been run about 1,000 miles. It was loaded with full equipment and four passengers, and weighed en route, scaled 3,800 pounds with and 3,230 pounds without passengers. The low gear ratio is 11.75 to 1, intermediate 7 to 1 and high 4 to 1.

Two Sunbeams May Enter Indianapolis Race

INDIANAPOLIS, IND., Dec. 5—Despite the war, several European entries for the next Indianapolis 500-mile, May 29, already seem certain. Darius Resta, one of the best of the foreign pilots, has written the speedway management that he, together with either Jean Chassagne or K. Lee Guinness, expects to bring over a pair of Sunbeams that will guarantee some extremely fast competition.

All three of the drivers mentioned are ineligible for army service, and hence will have no trouble getting away. At present their only problem is to get the consent of Louis Coatalen, the Sunbeam designer, to the venture, which, however, they expect to do with little difficulty.

The cars are the ones which competed in the 1914 Grand Prix de France. Showing a piston displacement of approximately 276 cubic inches, they come well within the limits prescribed by the speedway management. They are capable of speeds up to 110 miles an hour.

Milwaukee Show, Jan. 8-14; 83 Exhibitors

MILWAUKEE, WIS., Dec. 8—The 1915 Milwaukee motor show, January 8 to 14, will occupy by far the largest area of any of the six expositions that have preceded it. The show committee of the Milwaukee Automobile Dealers' Assn. has arranged for the use of 51,750 square feet of floorspace in the Milwaukee Auditorium, the leases calling for the entire main arena, Juneau, Kilbourn and Walker halls, the main arena basement, north and south rest rooms and the entire corridors around the arena. Eighty-three firms will exhibit.

COLUMBUS, O., Dec. 8—The annual Columbus Automobile Show which will be held in the Memorial Hall the week starting January 30 will be under the auspices of the Columbus Automobile Club and the Columbus Auto Trades Assn. The joint committee in charge of the show consists of J. P. Gordon, chairman, Ira Madden, vice-chairman; E. B. Coats, secretary; L. M. Browne, treasurer, and M. A. Pixley. In all fifty-five different cars will be shown including electric and gasoline passenger cars and motor trucks. Accessories will be displayed in the balcony.

28 More Exhibitors for National Shows

3 Car Makers and 25 Accessory Firms Added—Decoration Plans Are Complete

NEW YORK CIITY, Dec. 8—The names of three makers of cars and twenty-five makers of accessories have been added to the already long line of exhibitors for the National shows in New York and Chicago. Of the car makers, only the Remington Motor Co. will exhibit at both shows, the other two will exhibit at Chicago only. The complete list is given herewith.

The work of decorating Grand Central Palace for the Fifteenth Annual National Automobile Show to be held January 2 to 9, began this week.

The dominant colors will be white, gold and crimson. As usual, the signs at each booth will contain merely the name of the car, and these will be uniform throughout. In the accessory department, the signs will contain the name of the exhibitor. More than 200 men are engaged in painting the signs, building the pillars and casts, and arranging the floral decorations.

Manager S. A. Miles plans to have the setting for the cars in the Coliseum and Armory in Chicago one of the most ornate ever devised for an automobile show in Chicago. An old English garden will be the theme of decorations at the Coliseum and no detail of the effect will be overlooked.

New Overman Tire Company Is Organized

NEW YORK CITY, Dec. 8—The Overman Cushion Tire Co., New York City, with $150,000 capitalization, has been formed to succeed the Overman Tire Co., which is in the hands of receivers. The officers of the new company are: President, C. A. Taussig, an attorney; vice-president and sales manager, J. B. Bleiler, formerly an Overman salesman; treasurer and general manager, Max C. Overman, founder of the defunct company; secretary, Alexander Clogher. The company will discontinue the pneumatic tire with which it supplemented its cushion tire and will manufacture the cushion type only. The old company's factory in Passaic, N. J., has been discontinued and the new company is working temporarily in Belleville, N. J., with a New York office and store rooms at 250 West Fifty-fourth street.

DETROIT, MICH., Dec. 4—The first meeting of creditors of the bankrupt Detroit Electric Appliance Co., was held yesterday at the office of referee in bankruptcy Lee E. Joslyn. The inventory of the defunct concern was made public and shows that according to the books of the company the assets are worth $324,967.94 while according to the Detroit Trust Co., receiver, the value of the assets is only $168,015.72. The liabilities are shown by the bankrupt company to be $324,-967.94 while the Detroit Trust Co. has placed them at $90,-957.19. According to three special appraisers the tangible assets are valued at $35,207.

Premier Assets $307,376.50—Liabilities $508,468.52

INDIANAPOLIS, IND., Dec. 7—Frank E. Smith, receiver, has filed with Albert Rabb, referee in bankruptcy, a statement of the assets and liabilities of the Premier Motor Mfg. Co. The report is a voluminous one, covering about 100 typewritten pages and goes into the most minute detail.

According to the report, the total liabilities are $508,468.52 and the total assets $307,376.50. The plant is being operated, under direction of the United States Court and the receiver has been doing a very satisfactory business.

The liabilities include unpaid wages amounting to $5,774.77; priority debts amounting to $13,846.96; secured debts amounting to $809,062.54 and unsecured debts amounting to $160,048.84. The Fletcher American National Bank of this city holds contingent notes amounting to $107,047.68, secured by unsold cars which the receiver estimates are worth $82,137.50.

The assets include real estate valued at $50,050. The receiver does not state at what value he holds the patents and copyrights. The remainder of the assets include sums due from agents and officers of the company and due from other sources.

The receiver has paid all current wages due since he has been operating the plant. The item of unpaid salaries and wages mentioned was contracted before the receiver was appointed.

CINCINNATI, O., Dec. 5—Edgar Daniels, doing business as "The Multi-Letter Shop," and the "Daniels Auto Supply Company," at Dayton, O., Saturday filed a petition of voluntary bankruptcy in the United States Court at Cincinnati. He has liabilities of $3,596.55 and assets of $2,883.94, of which he claims $500 exempt. His assets consist of stock in trade, $655; fixtures, etc., $809; debts due on open accounts, $343, and vehicles, $75.

INDIANAPOLIS, IND., Dec. 8—Adrian Hamersly, president, has brought suit in the superior court at Indianapolis asking the appointment of a receiver for the Hassler Shock Absorber Sales Co. on the ground that the concern is insolvent and owes him $1,435.90.

NEW YORK CITY, Dec. 9—Smith-Haines, dealers in automobile supplies in this city, at 176 Broadway, have assigned for the benefit of creditors to H. B. Wilson, Jr., H. S. Hechheimer and Elmer Engield. The firm is composed of D. R. Smith, F. A. Haines and Frederick Ray.

LISBON, O., Dec. 5—Charging that the East Palestine Rubber Co. is on the verge of insolvency and in imminent danger of becoming wholly insolvent through mismanagement, A. E. Burnett has filed an action in the common pleas court here asking that a receiver be appointed by the court to protect and manage the property of the company. The company manufactures automobile tires.

XENIA, O., Dec. 5—The Hawkins Cyclecar Co., has filed in the Common Pleas Court a dissolution suit, claiming that the purpose of the corporation had failed, in so much that it had been unable to sell a manufactured product.

In compliance with the law, which requires that 3 months elapse between the time of the petitions and the hearing, the date of the trial was set for February 27. W. L. McAllister was appointed by the court as Master Petitioner, to hear complaints and receive claims against the company.

Blomstrom Receiver Is Awarded $46,106.75

DETROIT, MICH., Dec. 5—A suit for alleged breach of contract yesterday ended in the Circuit Court in the awarding of $46,106.75 to Julian G. Dickinson, receiver for the defunct Blomstrom Mfg. Co., against Fred Postal, owner of the Griswold Hotel, Detroit, and against Henry Bowen, a business man of Saginaw, Mich.

The complaint of the receiver against Postal and Bowen was that they had agreed in 1909 to take over the assets of the Blomstrom concern and to form a new company to be known as the Lion Motor Car Co. All the gyroscope motors made by the Blomstrom company were to be taken over by the new concern but it is charged that this was not done by the new company which made another type of motor car.

The stockholders of the Blomstrom company were to receive stock to the full value in the Lion company. After the incorporation of the Lion Motor Car Co., it is alleged that Postal and Bowen did not keep their contract.

During the present trial which lasted about 1 week the gyroscope motor was tested before the court and the jury.

Factory Miscellany

POPE Rents 13,000 Sq. Ft. Factory Space—Colonel George Pope, receiver of the Pope Mfg. Co. in the Connecticut jurisdiction, has rented the top floor of the Capitol avenue factory, Hartford, Conn., comprising about 13,000 square feet of floor space, to the Smith-Worthington Co., that city. The Smith-Worthington Co. is engaged in the manufacture of harnesses and saddles, and that this concern should need space in the Pope Building is explained by the fact that large orders for saddles, presumably from powers at war in Europe, have been received. For a long time past there have been various rumors as to the outcome of the property, part of which is now occupied by the Hartford Motor Car Co., the prime movers of which are Charles E. and Wilbur C. Walker, both former officers of the Pope company, who purchased of the receiver the parts making rights. Early this week it was stated that the Pratt & Whitney Co., a subsidiary of the Niles, Bement & Pond combination, wanted to rent a portion of the Pope factory. However, nothing came of the matter. The Pratt & Whitney company is now working off big orders for the Chinese, English and Russian governments, and needs room badly. Arthur L. Shipman, counsel for Receiver Pope, said this week that an offer to lease the factory had been made some time ago, the lease to run from 1½ to 2 years, but because the Pope real estate must be sold to satisfy creditors the counsel said that the offer had been turned down. The impression becomes the stronger from day to day that the Pope factories will eventually be acquired by some of Hartford's prosperous industries. It would not be at all surprising if the Pratt & Whitney company secured the property, as it adjoins their present big works.

New Bergdoll Plant in Trenton—The Bergdoll Automobile Co., Philadelphia, will erect a large manufacturing plant at Trenton Junction, N. J., near there.

Milwaukee Plant Suffers Fire Loss—The plant of the American Metal Products Co., 3102 Lisbon avenue, Milwaukee, Wis., was damaged $10,000 by fire on November 28. Arrangements are being made to resume production at once.

New Transmission Co.—J. G. Williams, of Trenton, Mich., and W. D. Gould, of Detroit, Mich., were in Sandusky, Mich., recently, trying to interest local business men in a new concern which is to make automobile transmissions. The company is to be known as the Ideal Gear Transmission Co., and will locate there if sufficient capital is raised by local business men.

Big Engine Shipment for Australia—The Affiliated Manufacturers' Co., 602 Caswell block, Milwaukee, Wis., a large selling organization handling a diversified line of products, has received an order for $10,000 worth of gasoline engines for shipment to Australia. It marks the resumption of the company's foreign business, interrupted in July by the outbreak of the war.

Ford Benefits Far-Reaching—As a result of 10 months' operation of the Ford profit-sharing plan, employees of the automobile manufacturer have purchased, on contract, homes valued at $5,000,000, upon which they have made payments aggregating $1,200,000, have taken life insurance to the amount of $3,000,000 and have saved on an average of $48.76 per month each, which is either in savings banks or invested in real estate. About 9,200 employees are under the profit-sharing plan. More of them are coming up to the qualifications constantly. Since the plan went into effect the average gain per man in bank deposits has been 130 per cent; in life insurance, 86 per cent; in homes owned, 87 per cent. There is a marked increase in the number of naturalized citizens and a radical improvement in their habits, morals, health, mentality and living conditions.

Manufacture Sheet Metal Wiring Machines—The Magee Sheet Metal Machinery Co., Detroit, Mich., recently incorporated, is going to manufacture sheet metal wiring machines specially used in wiring fenders. Several sample machines have been tried out by one of the largest automobile manufacturers, and it is stated, have resulted in the saving of more than $40 a day through their use. The new machine will run 1,750 feet of wire during a 9-hours working day, wiring 250 fenders of the particular type used on the cars made by that manufacturer. Where the cost had been 6 cents for wiring the fenders of those cars according to the old method, the new machine has brought this cost down to 1 1-2 cents. Another advantage of the Magee machine is that it requires but a rather small floorspace, one man operating the machine within a space of 16 square feet, it is claimed. For the time being the machines will be made only per contract and later a factory will be built.

The Week in  the Industry

Motor Men in New Roles

FERGUSON Heads Grant-Lees Sales—Richard Ferguson has been placed in charge of the sales of the Grant-Lees Machine Co., Cleveland, O. He remains also as manager of the buying and production departments.

New Apperson Branch Manager—C. E. Wilbar has been appointed manager of the Pittsburgh, Pa., branch of the Apperson Bros. Automobile Co., Kokomo, Ind.

Burke Joins Gray and Davis—W. W. Burke, better known as "Billy Burke," has been appointed New York branch manager of the Gray and Davis Co., of Boston.

LeCain in Business—Jack LeCain has formed a company in Boston, Mass., to handle the Master carbureter and other specialties with headquarters on Massachusetts avenue.

Homan Representing Gould Battery—C. C. Homan, who was general purchasing agent of the Willys-Overland Co., Toledo, O., is now a special sales representative of the Detroit, Mich., department of the Gould Storage Battery Co.

Lurie Joins Colt-Stratton—Robert Lurie, for a number of years connected with the used car business along automobile row in New York City, has been made manager of the used car department of the Colt-Stratton Co., that city, with headquarters at 1770 Broadway.

Neel Heads Philadelphia Corp.—The following officers of the Automobile Sales Corp., Philadelphia, Pa., distributer of the Cadillac, were elected recently to serve for the ensuing year: President, P. L. Neel; vice-president, S. Stankovitch, Jr.; secretary, J. B. Dickson, and treasurer, H. R. Shock.

McLaughlin Sales Manager—E. J. McLaughlin, formerly sales manager of the Saxon Co., in New York territory, has been appointed general sales manager of the Hudson-Bender Motor Car Co., Kane, Pa., distributor of the Hudson in thirteen counties of Pennsylvania and three in New York State.

Studebaker Firestone's N. Y. Manager—C. D. Studebaker has been appointed manager of the New York City branch of the Firestone Tire & Rubber Co., Akron, O., succeeding J. J. Jordan, who goes to Europe to take charge of the Firestone company's European department and develop its foreign business.

Coates Heads Kalamazoo Assn.—At a meeting of the Kalamazoo Automobile Dealers' Assn., Kalamazoo, Mich., G. A. Coates, representative of the Haynes Co., was re-elected president; J. M. Van Loon, representative of the Cadillac Motor Car Co., was elected secretary, and William Harlow, of the Ford company, treasurer.

Huyette Re-elected Quaker Club Pres.—The ninth annual election for officers of the Quaker City Motor Club held in the Hotel Walton, Philadelphia, resulted in the re-election to the presidency of P. B. Huyette. In addition to Mr. Huyette, the following were the other successful candidates: Vice-presidents, G. D. Bartlett and A. H. Wetherill; treasurer, R. L. Murray, and secretary, W. E. Stagg.

Fisher's Standard Truck Appointment—The Standard Motor Truck Co., Detroit, Mich., announces the appointment of F. J. Fisher to the position of secretary-treasurer in place of W. K. Ackerman, who is no longer an official of the company. The other officers of the Standard company are Albert Fisher, president; U. A. Fisher, vice-president, and E. M. Elliott, general sales manager.

New Empire Manager—J. B. Todd, who has been connected with the Empire Rubber Co. for more than 7 years and for several years manager of its New York branch, at 240 West Fifty-fifth street, has severed his connection with the concern to take an important position with Marshall, Wood & Co., of Plattsburg, N. Y., dealer in automobile supplies and hardware. The new manager of the New York branch of the Empire Rubber Co. will be Thomas O'Callaghan, Jr.

—

Garage and Dealers' Field

Philadelphia Overland Moves—The Overland Motor Co., Philadelphia, Pa., will shortly move to much larger quarters at 323-325-327 North Broad street and 1339-1347 Wood street.

Remy Service Station Changed—The Remy Electric Co. has changed its service station in Los Angeles, Cal. The station is now conducted by the Hucks Auto Electric Co., 627 West Pico street.

Williams Co. Equipping—The plant of Williams & Co., 58 Parks street, Niagara Falls, Ont., is to be equipped with machinery for the manufacture of carbureters and equipment for general garage and automobile repairs.

Represents Master Carbureter—The Drenco Machine Co., Inc., New York City, has taken on the Master carbureter and will represent it in the metropolitan district, taking in Northern New Jersey, Southern New York counties, Long Island and adjoining Connecticut territory.

Fifty Hours' Service Free—E. M. Holmes, an Indianapolis, Ind., dealer, is giving a coupon book good for 50 hours of service to each person buying a motor car through his agency. The coupons are good any time during the life of the car. Mr. Holmes is agent for the Detroiter and Monarch.

Flanders Moves in Detroit—The F. E. Castle Co., Detroit, Mich., factory representatives of Edmunds & Jones Mfg. Co., the Rands Mfg. Co. and recently appointed representative for the Paris Tire & Rubber Co., Newark, O., and the Sterling Spring Co., has moved into new offices and salesrooms at 872 Woodward avenue.

Diamond Establishes Wholesale Depot—A wholesale depot for the distribution of Diamond tires to dealers located in Washington, Oregon, Idaho, Montana and the Canadian provinces of British Columbia and Alberta has been established in Seattle. Heretofore this field has been supplied from the Diamond branch in San Francisco.

Cleveland's New Accessory Firm—The Fen-Kar Co. has been organized in Cleveland, O., by H. J. Farr, J. A. Fenner, C. W. Fenner and W. F. Martin, respectively president, secretary, treasurer and manager of the company. The firm has salesrooms at 2121 East Fourth street, and does a wholesale and retail automobile accessory business.

Regal Agent's Novel Advertising Scheme—H. P. Lorbach, the Regal agent at Circleville, O., has hit upon a novel advertising scheme which has brought a lot of publicity. He held a guessing contest on the number of beans in a jar, giving to the winner a certain credit on the amount of money required for a new car. One man guessed the exact number of beans in the jar.

McClurg to Make Tires—The McClurg Rubber Co., Coshocton, O., has been incorporated with a capital of $250,000 to manufacture automobile tires and tubes by J. S. McClurg, W. A. Himebaugh, O. D. Tucker, J. M. McClurg and William L. Davis. Plans are being made to take over the plant of the S. & M. Rubber Co. and start operations on a large scale by January 1.

Goodyear Moves to L. I. City—The Goodyear Rubber Tire Co., of New York, has moved its headquarters from Broadway and 67th street, New York City, to its big warehouse and service station in Long Island City. This building occupies a plot of 50 by 268 feet, and is six stories in height. The company sells only at wholesale, but will continue to maintain a stock of tires and a branch service in Manhattan.

Overland's Seattle Branch Adds—The J. W. Leavitt & Co., Seattle, Wash., Pacific coast distributors of Overland automobiles, states that two stories will be added to the corporation's plant in Seattle. The present home of the Leavitt company in Seattle provides 21,000 square feet of floor space, and, with the two additional stories, there will be available a total of 36,000 square feet of room. The improvement will cost upwards of $12,000 and will be completed by spring. The building will be of brick and steel. The two new floors will be devoted to the rebuilding and painting of used cars.

Bartles Oil's New Station—The Bartles independent oil interests have decided to establish a large distributing station at Ashland, Wis., to serve the vast Northwest Wisconsin territory. The Bartles-Dadmun Oil Co., capital stock $25,000, has been organized by C. A. Maguire, of Duluth and John Dadmun, of Milwaukee, and will spend from $10,000 to $15,000 in the erection of permanent offices, tanks, warehouse, etc. Mr. Dadmun will be active manager and move to Ashland. The Bartles associated companies now have stations and offices in Milwaukee, St. Paul, Peoria, Dayton, Waterloo, Ia.; Stillwater, Wilman, Minn.; Grand Forks and Beach, N. D., and Crookston, Minn.

Accessories for the Automobilist

STEWART Warning Signal — The Stewart hand-operated warning signal which is made by the Stewart-Warner Speedometer Corp., Chicago, Ill., has been reduced to $5. This horn, Fig. 1, is of substantial construction, and each gear is furnished with a steel bushing on which the bearings are carried. Lubrication is effected by means of an oil-soaked, felt pad which rubs against the bearings and wheels continuously. This signal has a double bracket so that the horn remains solid no matter how severe the pressure. The bracket is made with a swivel, one part of which fastens to the rail of the car and the other part holding the horn is swiveled on it so that the horn can be adjusted to suit. A high gearing is employed so that one full depression of the plunger produces 192 distinct sound impulses.

C-C Shock Absorber—The Cox Brass Mfg. Co., Albany, N. Y., has bought out a new shock absorber for Fords to be sold at the unusually low price of $8 per set of four and $4.50 per pair.

The construction of the C-C is extremely simple—a slotted spring cage with two belt holes, through which the belts are run, displacing the Ford shackle belts, makes the attachment. Inside the spring cage, a sturdy helical spring of finely tempered steel carries the weight of the car, cushioning, softening and smoothing out irregularities of the road. Inside the big spring—a smaller one—a compensating spring wound in the opposite direction, assists the main spring. A nut at the top enables one to adjust, at will, the C-C shock absorbers to meet the peculiarities of any Ford.

The action of the C-C is such that when the car receives an extremely severe jolt, the rebound is checked by means of a spur so designed that automatically the entire capacity of both springs is brought into action.

The C-C shock absorbers can be attached without removing the wheels. The Cox Company claim that these shock absorbers can be put on by any one in less than an hour.

Johns-Manville Clocks—The H. W. Johns-Manville Company has just announced the addition of two new type clocks, Fig. 3, to their extensive line of automobile accessories, one for flush and one for dash board mounting, both embodying the latest approved ideas in clock construction in an 8-day fully-guaranteed time piece.

These clocks have been designed so that the mounting screws, winding keys and setting knobs are hidden from view and fully protected; therefore easily cleaned and practically proof against tampering.

The movement, which is of the lever escapement type, is enclosed in a dust,

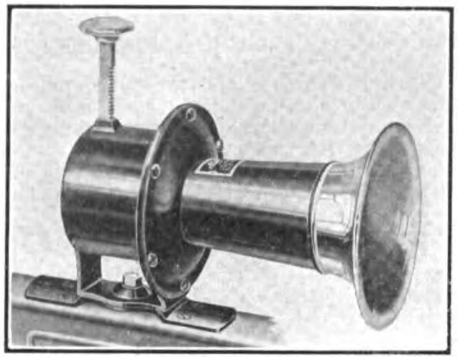

Fig. 1—Stewart warning signal selling for $5

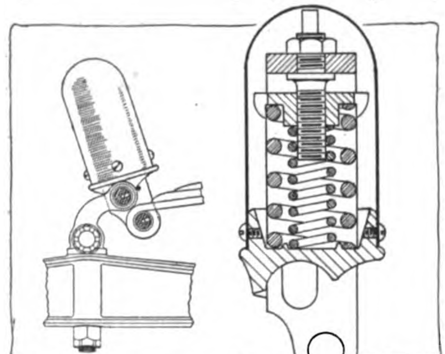

Fig. 2—Cox shock absorbers for Fords at $8 per sent of four

dirt and moisture proof case that is permanently secure to the clock bezel. This unit, in turn, is carried in an outer case and locked by a patented device that makes it possible to remove and replace same by a simple quarter-turn. Both winding key and setting knob are permanently attached to movement.

The purchaser of the J-M Automobile Clock has a choice of several finishes, in black with brass, nickel or gun metal flange, with either black figures on white porcelain or silver dial or with white figures and hand on black dial.

Kellog Turbine Muffler—Unlike the muffler now employed to silence the exhaust, the new Kellog turbine muffler, Fig. 4, not only destroys the explosive noise from the motor but materially helps the discharge of exhaust gases from the motor.

A simple turbine wheel A is mounted in the path of the exhaust. Just forward of this wheel is an opening or bypass which leads to the center of the turbine wheel. The rapid turning of the turbine wheel caused by the exhaust of one explosion produces a powerful suction which helps suck out the exhaust gas of the next. In other words the turbine is a flywheel which tends to make the flow of exhaust gas even, smoothing out the high-pressure waves that occur at the instant when the exhaust valves open. A simple baffle plate B further muffles the exhaust.

The device is manufactured by the Kellog Mfg. Co., Rochester, N. Y.

Graphalloy Self-Lubricating Bushings—Bearings which do not require lubrication are made by the Graphite Metallizing Corp., Yonkers, N. Y. Graphalloy is a product consisting of graphite impregnated with a molten metal and may be used wherever the duty is light. Light duty bearings include fan, timer, magneto and pump bearings. The basic element of graphalloy is pure graphite and the object in adding metal to it is to solidify the product so that it may be machined into bearings or bushings of any desired form and which will have the requisite strength and durability. The standard bearing consists of solid graphite rods impregnated with a babbitt of special composition. This metal has adequate strength and a low coefficient of friction.

Four-in-One Auto Heater—A heater of the same type is made by the Auto Heater Co., of America, 1148 Bedford avenue, Brooklyn, N. Y. It is known as the Four-in-One Heater, and is made supplied with either one or two registers, as desired. With two, one is placed in the panel under the front seat and the other is put in the tonneau floor. The heat is regulated by a valve which is placed in the exhaust line and which diverts more or less of the heat into the heater. Connection between the valve and the heater is through a large diameter flexible piece of tubing and the coils are suitably covered by a metal grating.

Fig. 3—J-M flush automobile clock

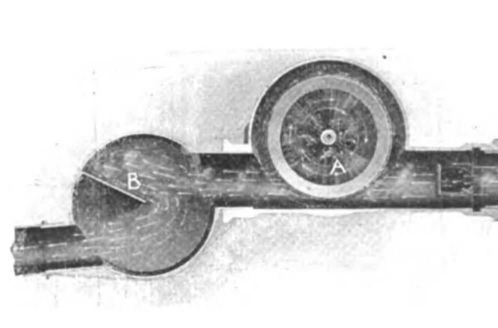

Fig. 4—Kellog turbine muffler

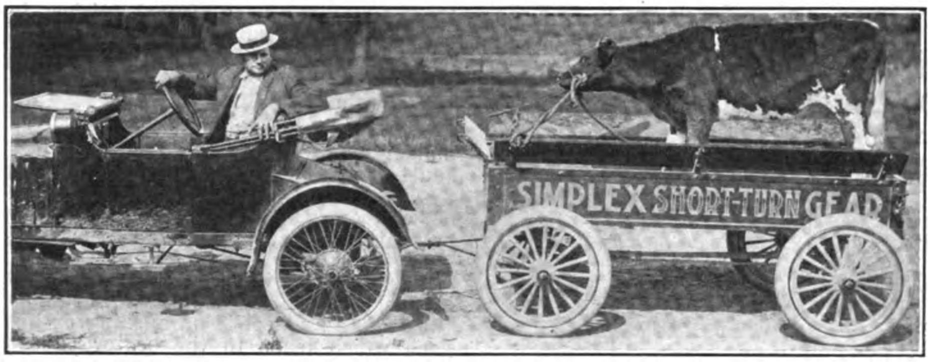

Fig. 5—Simplex trailer. The one illustrated is the 1,000-pound size

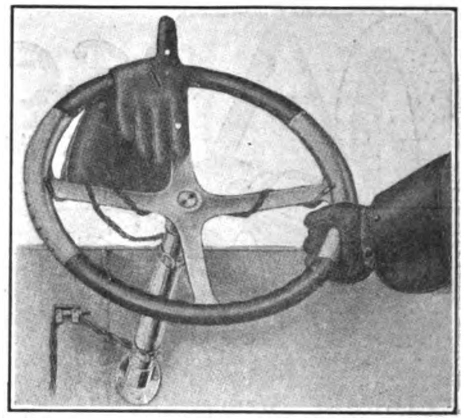

Fig. 6—Carron electrically heated gloves

Dash Board Primer—The type of primer made by the Indiana Accessories Co., Indianapolis, Ind., consists merely of a tank on the dash which connects with the manifold by a small pipe, the flow of fuel being controlled by a small valve at the base of the tank. It is priced at $2.50 finished in nickel.

Simplex Trailer—A four-wheel trailer adapted to light cars and fitted with rubber tires has been brought out by the Simplex Short-Turn Gear Co., Indianapolis, Ind. It is made in tow capacities, 700 and 1,000 pounds.

The smaller one is fitted with solid tires and is designed for speeds of 20 miles per hour while the larger one is equipped with pneumatics and may be hauled at speeds up to 30 miles per hour. One - thousand - mile plain bearing axles are used on the smaller model and ball bearings are employed on the larger.

Carron Electrically Warmed Gloves—Gloves, Fig. 6, which incorporate in the lining a tough but flexible electrical circuit are made by Carron & Co., 75 Beekman street, New York City. This electrical circuit terminates on the surface of each forefinger in a small metal disk and at the thumb in a similar disk. When the hand grasps the wheel these small disks are brought into contact with the thin plates on the upper and under surfaces of the steering wheel which form the terminals of the wires from the storage battery. This circuit is closed by this contact and the current is led through the lining and across the back of the hand and all of the fingers. A 6-volt circuit is required.

Fuel Indicator—A device to tell the fuel consumed on a given trip and also the total amount of fuel used since the installation of the device is shown in Fig. 8. In other words this device bears the same relation to the measurement of the fuel that an odometer bears to the mileage covered. There is an indicating mechanism on the dash on which are two dials, one for trip consumption and the other for season.

With this device and the speedometer it is easily possible to figure the mileage per gallon on any trip or the mileage per gallon for the whole season.

It is stated that the construction of the device is simple, and is based on a principle that has been used with success on water meters. The device is made by the Fuel Meter Co., 937 East 54th street, Chicago, Ill.

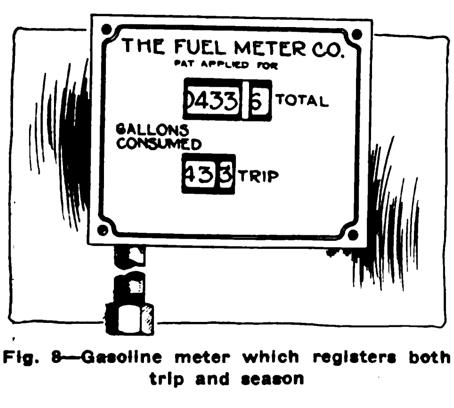

Fig. 8—Gasoline meter which registers both trip and season

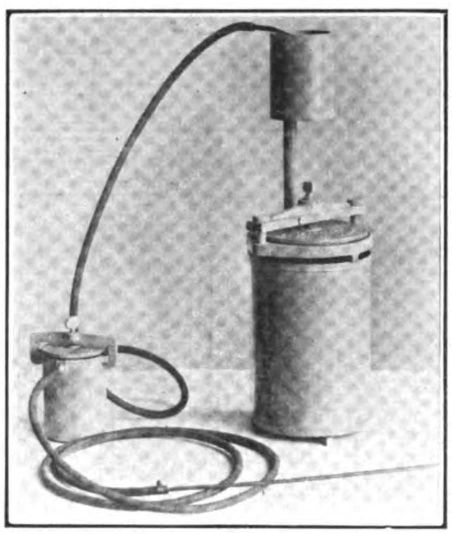

Fig. 7—Progressive carbon remover which generates its own gas

Progressive Carbon Remover—A complete oxygen-carbon removing outfit is manufactured for $7.50 by the Progressive Mfg. Co., Reading, Pa. It not only generates its own gas but forces it through a nozzle into the cylinders of the motor. The complete outfit is shown in Fig. 7. The main parts are a cylinder underneath which is an alcohol lamp. A special compound furnished with the outfit is placed in the cylinder and the alcohol lamp is lit. Then oxygen is generated and the gas passes to a water container where the oxygen is collected and then it is passed through another container where it is purified. From thence it is carried to the cylinders. The operation of burning out the carbon is done in the ordinary way. The cylinder is allowed to fill with oxygen and the carbon is lighted by a match or taper. Oxygen is supplied until the carbon is completely burned. It is wise to remove the spark plugs before the carbon is burned out because the heat may be sufficient to crack the porcelain although it is not enough to injure the motor. Additional compound may be obtained for 75 cents.

Apex Oil Cup—Claiming that bearings which do not revolve cannot be lubricated properly by grease, the J. E. Lonegran Co., 211 Race street, Philadelphia, Pa., has brought out the oil cup shown in Fig. 9. The cup consists of a suitable shell which contains cotton waste for holding the oil. This shell is provided with a cap which has a filling slide so that lubrication may be easily effected. It is stated that one filling every 500 to 1,000 miles is sufficient. The rate of feed is regulated by the amount of waste in the cup. For instance, it is recommended that for spring bolts the cup be half filled. Three finishes, dull brass, finished brass and nickel are offered and the cups are made in .125 and .25-inch sizes. Prices vary from 50 to 80 cents.

Disfice Fibre Specialties—Many vulcanized fibre specialties suitable for motor car construction are made by the Diamond State Fibre Co., Elsmere, Del. Vulcanized fibre high-tension wiring cleats are made for wiring installations and wiring tubes both straight and curved are manufactured for housing wiring. It is stated that this material is oil-proof and can therefore be used for gaskets and washers. It may be used for speedometer gears thus reducing the noise and increasing the life of the parts. It is stated that the sheet fiber may be used in place of leather or sheet metal for fenders or even bodies and that it may be made into mud pans.

Jiffy Primer—The Crary Co., 650 Woodward avenue, Detroit, Mich., is manufacturing a motor primer under the name of Jiffy. It consists of a fuel tank which is mounted on the dash and which connects with the manifold through a small pipe. The flow of fuel is controlled by a small needle valve. It sells for $2.50.

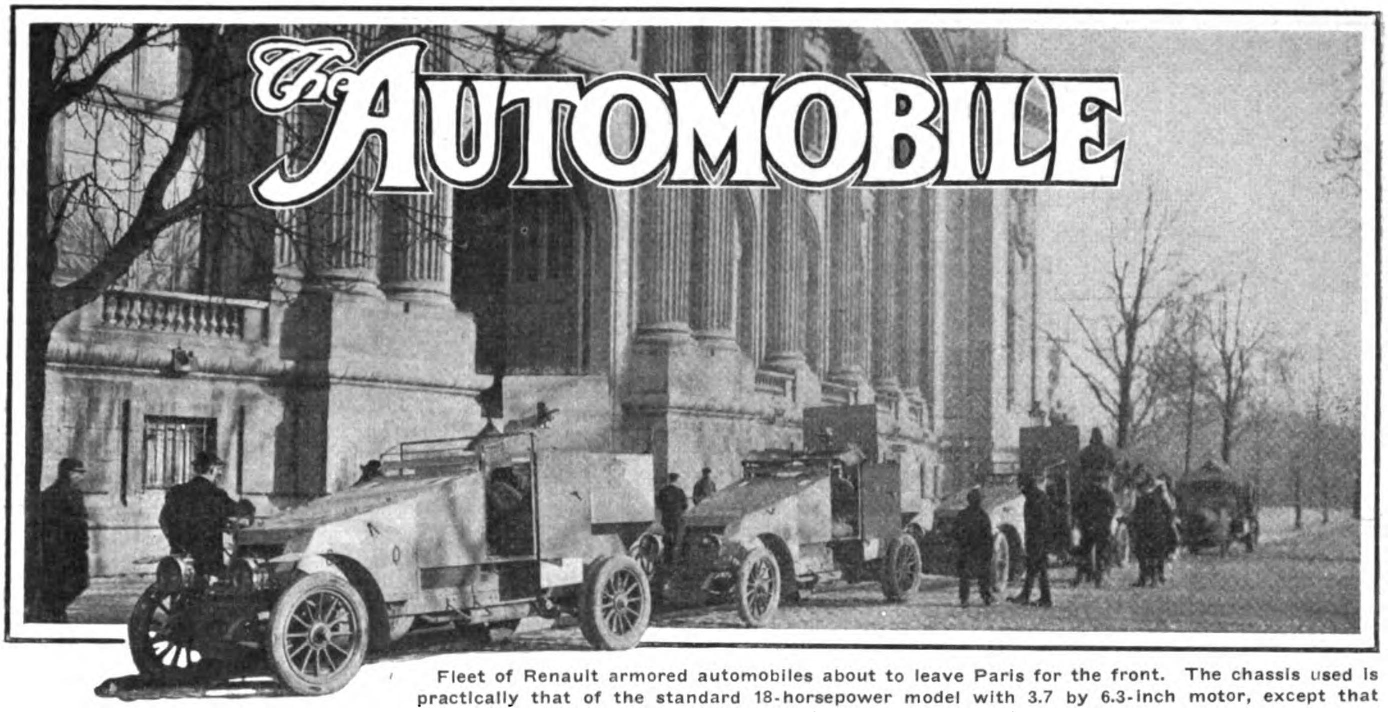
Vol. XXXI New York—Thursday, December 17, 1914—Chicago No. 25



Fleet of Renault armored automobiles about to leave Paris for the front. The chassis used is practically that of the standard 18-horsepower model with 3.7 by 6.3-inch motor, except that the rear axle has been changed to permit the use of twin wheels

France Builds Armored Cars

Traveling Forts Prove Impractical Under Present Conditions —Light Weight Essential—Armored Touring Cars, 2-Ton Truck Chassis and Light Cars with Minimum Plating Do Best Work—Wheels Not Protectcd

By W. F. BRADLEY,
Special Representative of THE AUTOMOBILE *with the Allied Armies in France*

PARIS, Nov. 28—In common with many other French firms, the Renault company has received an important order for armored automobiles. The first series has just been delivered and has been taken over by the French naval brigade operating in Belgium along the coast line. The chassis is the firm's 18-horsepower model having a four-cylinder motor 3.7 by 6.3 inches bore and stroke. It is mounted on detachable wood wheels with pneumatic tires, twin wheels being used at the rear. With the exception of the change necessary in the rear axle to accommodate twin wheels, the chassis is practically standard.

Cars All Protected

Armor plating protects the whole of the car with the exception of the tires and wheels, which are left fully exposed. The method of construction is to place steel ribs at rather wide intervals from frame member to frame member, above the motor and as far to the rear as the steering wheel. Steel plates are attached to this framework by means of bolts and winged nuts. This makes it possible to quickly dismount any plate if it is necessary to examine the mechanism. The housing completely covers both the motor and the radiator, which is behind the power plant, as on all Renault cars.

As will be seen from the illustration the general shape of the Renault bonnet is maintained, but without the angles being rounded off. There is a gap in the forward portion of the housing to allow of air entering, the draft being assured by the flywheel fan. While this general arrangement might appear to be inefficient as regards cooling, it is worth noting that on the latest Renault models, intended to have been produced for the 1915 season, no radiator tubes are exposed, the sides and top of the bonnet being flush with the sides and top of the radiator. The capacity of this latter has

—*Copyright by Underwood & Underwood.*

Armored Autocars accompanying the Canadian troops at the time they were inspected by the King of England during his review of the forces at Bustard Camp, Salisbury Plain

been increased. While the cooling arrangements can hardly be considered ideal, they ought to be found sufficient for winter work.

A steel plate is carried in the extreme front, between the frame members, so as to protect the underpan, which with this system of cooling must be completely airtight so as to prevent the draft passing otherwise than through the radiator tubes. At the rear there is a similar plate, filling up the whole of the space between the frame members, and giving protection to the axle and differential housing.

Body Well Protected

The body is a box-like structure with a quick-firing gun pivoted in the center and having a rectangular shield. With the exception of a tool box under one of the overhanging panels on the left-hand side, the whole of the kit is under cover. The steering column is well raked so as to give the driver as low a position as possible. His protection consists of the scuttle dash, which consists of an inclined plane from the front of the motor to the steering wheel, where it is surmounted by steel louvres with a variable inclination. A complete set of spare tires is placed upright at the back of the driver's seat. No special seating accommodation is provided for the gunners. The crew of each car consists of three men.

Need for Armored Cars

No type of automobile has proved more useful than the armored car. Yet it is this branch of automobile application to warfare which had received least attention before hostilities were declared, and on which the army authorities even now possess the least knowledge. Of all the powers engaged in this war, Germany alone seems to have appreciated the armored automobile; but she was the only power prepared for an offensive war. And even her machine had the disadvantage of having been developed in the drawing office, and not on the road. The other nations in the war adopted armored automobiles after the outbreak of hostilities, and when they had seen what Germany was doing.

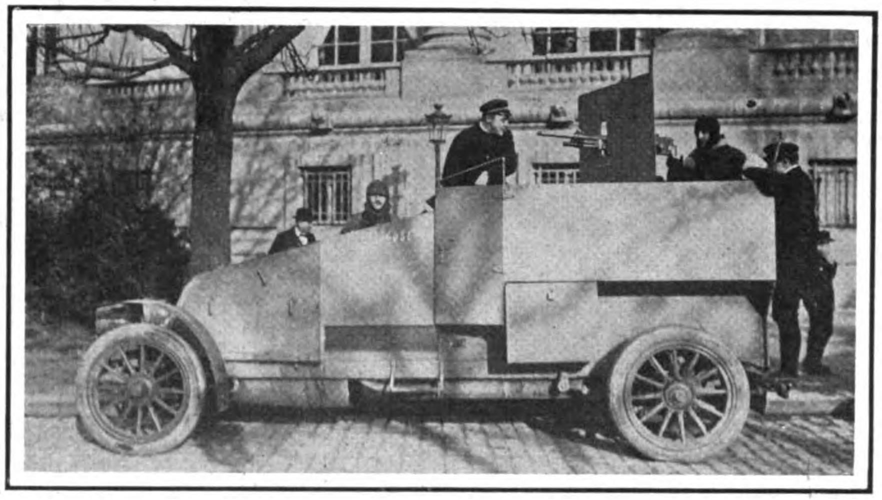
All Sorts of Cars Used

Every type of vehicle propelled by an internal combustion motor appears to have been thought suitable for receiving a gun and some armor plating. On the one hand we have the traveling German fortresses, standing 9 or 10 feet high, completely inclosed in steel, and probably weighing 8 or 9 tons, and on the other hand there are ordinary touring cars, taken out of private service and fitted with a quick-firing gun back of the rear seat, without an inch of protective plating. The German traveling fortresses might have been useful if the high road march to Paris had been carried out during the month of August, according to schedule. It is difficult to conceive of them making any progress on the secondary roads which have been cut up by 3 months' war, heavy rains, and some frost. The French touring cars with a gun in the rear might have been useful against savage tribes.

Armored cars generally have suffered by reason of their method of design. The artillery services have ordered or taken possession of a certain type of standard chassis, have put a gun on it and put plating around it without paying sufficient attention to the design as a whole. Weight is the enemy. Obviously it is a difficult matter to maintain a low weight if steel plating of adequate thickness has to be carried round men, gun and mechanical organs to make them proof against rifle bullets and shrapnel.



Renault armored automobile manned by French marines. The first series of these cars has just been delivered and taken over by the French naval brigade operating in Belgium. The chassis used is that of the 18-horsepower Renault model, the only change being the alteration of the rear axle to permit mounting dual tires

Two Types of Armored Cars

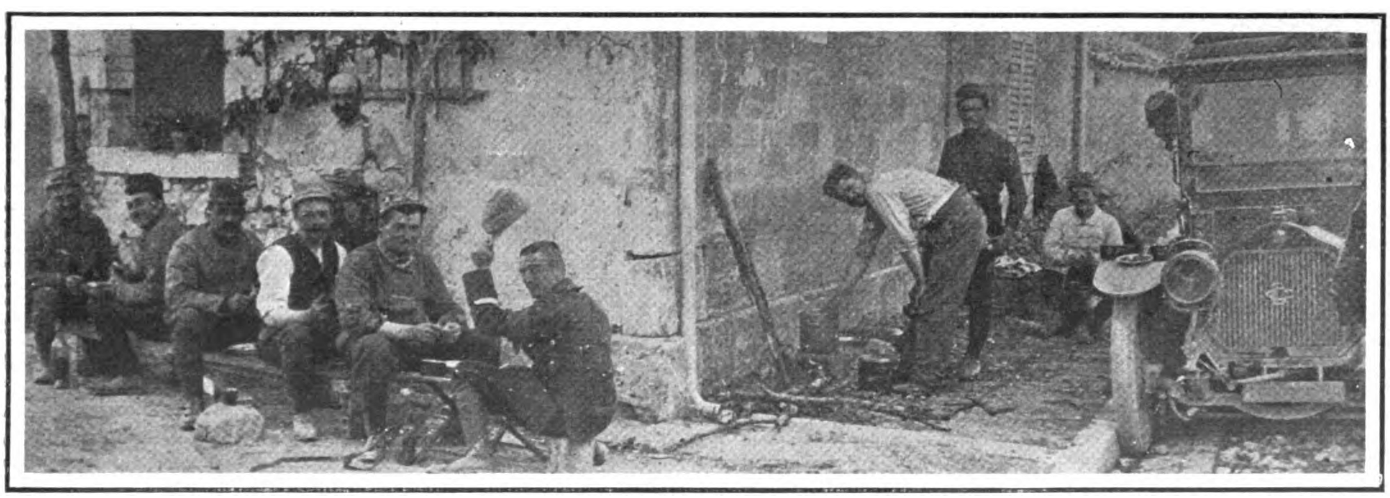
The extreme type, or traveling fortress is not suitable for warfare under the conditions pertaining at the present time. It must have first-class granite or macadam roads, and even in highly-developed Europe these are not always available. Results up to date show that two distinct types of armored automobile should be provided for. The first is a powerful touring car, or even a 2-ton truck chassis, completely incased, but without losing sight of the fact that weight must be kept down. The Belgians have some very good examples of this type of armored car. They have taken their more powerful touring car chassis, with motors approximately 4 by 6 inches bore and stroke and have built a suitable steel body on them. These machines are not intended to do cross-country work, but they will naturally have to operate on dirt roads and should have a reasonable clearance. In order to keep weight at a reasonable figure, the height should be as low as possible. It is quite possible to give all the protection required for the men and gun without exceeding a total height of 60 inches. The steering column is well inclined so as to bring the driver towards the center of the car, and in as low a position as possible. There is no difficulty regarding the seating accommodation, for the interior of the body is a single compartment. A roof is not required; while it is dispensed with on most of the cars now in the field, it is considered to be advantageous to have a partial roof, the center being open for the manipulation of the gun. Many of the Belgian machines have a turret revolving with the gun.

Protecting the Radiator

The motor and radiator must be completely protected. It has been proved that it is possible to do this without interfering with the cooling efficiency. With a correctly designed fan and a slightly larger radiator, enough air can be drawn in to keep the motor cool under the most disadvantageous circumstances. In most cases the bonnet is of such a design that it allows of the easy escape of the hot air under it without allowing shot to enter.

There is no necessity whatever to completely inclose the wheels, indeed to do so makes the car useless except on perfect roads, yet some protection should be provided. Detachable wheels are an absolute necessity. For war purposes wire detachable types have proved their superiority. On the heavier armored machines cast steel wheels are proving satisfactory.

A differential lock is proving to be a valuable



French army drivers preparing their dinner in a village near the firing line. The second man to the left of the water pipe is Albert Guyot, the Delage racing driver who drove in the Indianapolis race last May

Two 20-horsepower Daimler ambulance vans presented by Lord Furness to the Australian forces sent to the battle front in France

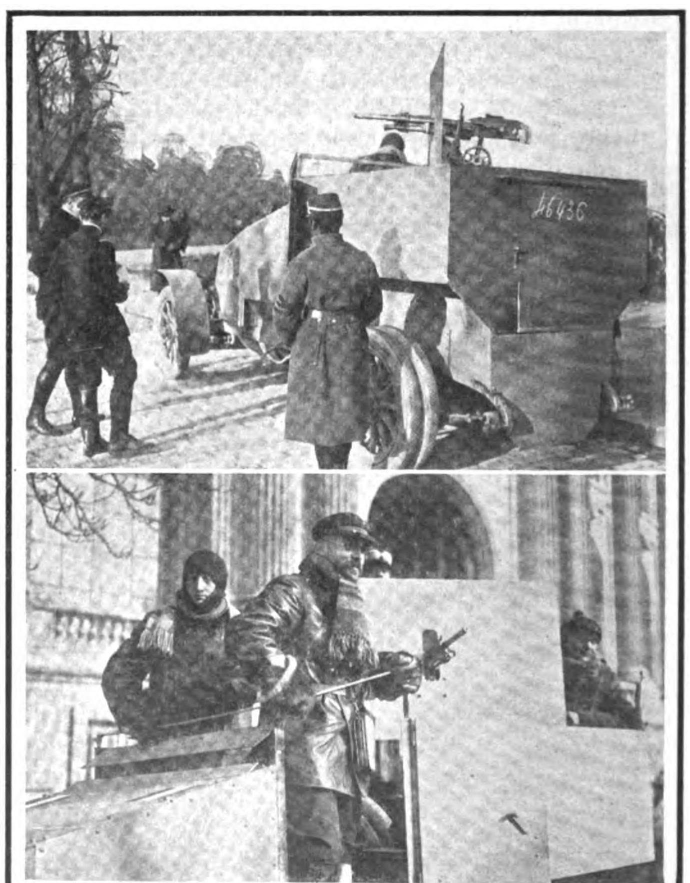
auxiliary. It is an obligatory fitting on certain types of French army tractors. The driver of an armored car soon asks for chains for his driving wheels, although he may never have used them in private service. Among the truck types which are being used as armored cars are the London omnibus chassis and French 2-ton trucks. While they are satisfactory as a whole, the bus chassis are unnecessarily big for carrying a single gun and three or four men. Their bulk is further increased by building the body with an overhang, so that it protects the wheels.

Light Armored Cars

The second type of armored automobile is the light car of the Ford class, with the minimum amount of plating. It is known that the French authorities have had a number of Fords under practical test, and it is quite possible that the order for them will have been placed before this story appears in print. These machines are intended to operate over any kind of road and to do a certain amount of cross-country work. The object of these cars is to extend the scope of the machine guns attached to cavalry and infantry regiments. The men who handle these guns carry them over every kind of country, and if the same work is to be done by an automobile, but of course with greater rapidity, ability to pass everywhere must be the main consideration. There cannot of necessity be much plating; protection of the main organs against rifle fire is the utmost that can be expected. Even this is not absolutely necessary. The machine gun sections make their way without any artificial protection, and the men who handle these cars will not run exceptional risks by doing the same.

Four-Wheel-Drive Suitable

Evidently there has been no time to produce the ideal armored automobile. It may be that plans are in hand, but if so, it will not be known until the completed machine has made its appearance. The four-wheel-drive has already proved its value and should be adapted to armored automobiles. A machine similar to the light four-wheel-drive tractors, of which the French are now making considerable numbers, would be ideal for this work. The present machine, however, is unnecessarily heavy, for it is designed to pull a useful load of about 6 tons. With the same design, however, and much lighter construction, an excellent fighting machine would be obtained. All on it need not weigh more than 3 tons.



Upper—Another view of one of the new Renault armored cars, showing the mounting of the machine gun behind the armor plate
Lower—French naval officers in one of the armored cars built by the Renault company for service with the naval brigade on the coast of Belgium

Such a machine, driven and steered at both ends, could have a speed of 30 to 34 miles an hour, which is ample for war requirements, and would be capable of traveling over any country on which a horse can draw a load. In addition to driving at both ends, it should have duplicate steering, so that the driver has only to turn from one wheel to another to travel stern first. Instead of the six forward speeds now used on these light tractors, there should be four forward and two reverse speeds. This will enable the machine to travel ahead at a rapid pace and will enable it to get out of difficulties from which it would otherwise be inextricable.

It is somewhat surprising that a vehicle of this type has not been already produced. Events have moved with greater rapidity than designers. The four-wheel vehicle has only just been perfected, but the French, who are responsible for the pioneer work in Europe, have not got any further than its application to heavy loads. The double-steering car, with a low and a high reverse, has also been in use for some time, but only for the purposes of smuggling along the Franco-Belgian frontier.

Cars for Big Guns

There are other applications of the armored automobile to artillery, but they do not come under the category of armored cars. The French, for instance, have some of their heavy guns mounted on special automobile chassis fitted with four solid struts capable of lifting the wheels clear, thus providing a solid platform. Further, many of the 155-millimeter guns are drawn by four-wheel-drive tractors instead of by horses. These, however, are only successful attempts to give greater mobility to artillery than is possible with the use of horses. There is no attempt at armor plating the vehicles. When the tractors have brought the guns into position they are put into a place of shelter in just the same way as horses. They are more easily concealed, however, than animals, and by means of their winches they have the advantage of being able to haul the guns out of a difficult position without actually exposing themselves.

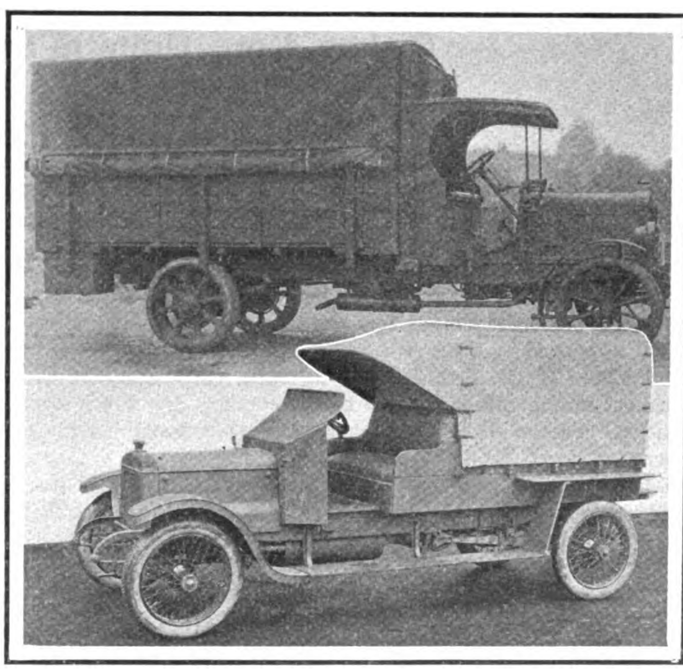
President of France Rides in German Car

PARIS, Nov. 27—President Poincaré left Paris this morning for his third visit to the troops in the firing line. As on the two previous occasions the French president traveled by automobile; indeed, Poincaré is such an enthusiastic motorist that he would not consent to any other means of locomotion. There is an entire absence of ceremony in these trips. The cortège consists of four automobiles. In the first is the director of the secret detective service and a couple of his assistants. He is followed by the president, riding on this occasion in a 70-horsepower Benz touring car—much to the displeasure of the ardent patriots aware of this fact. The presidential car is driven



Upper—The Daimler traveling workshop ready for the road. This carries a complete outfit for making repairs of all kinds

Lower—A 20-horsepower Daimler equipped with canopy top and shield for the driver. Note the shelf-type rear fenders by M. Romano, a well known French race driver who has done a considerable amount of work for the Gregoire company. Romano is a burly native of Marseilles, in which port he acquired from American sailors such a knowledge of American slang and such a refined American accent that he can easily pass for a citizen of the United States. Two officers of the presidential staff ride with Poincaré.

Non-Stop Runs Sure

The third car carries staff officers. The fourth is a Rolls-Royce driven by M. Journu, a Paris automobile salesman, accompanied by Georges Sizaire. The official function of Sizaire is presidential repairman. He has been selected for this post on account of his complete knowledge of automobiles, which enables him to discover the cause of a stoppage in less time than most men take to think about it. It should be mentioned, however, that Sizaire prides himself on the fact that the cars never have to stop on the road; at the end of each journey he gives them his personal attention and is certain of them making a non-stop run.

Preparations for the presidential visits to the army are kept secret; it is not until they are actually on the road that the drivers are given instructions as to direction. A fast pace is always maintained, the detectives' car running a certain distance ahead to warn sentinels of the approach of the president. These precautions are necessary in order to avoid attentions from hostile aeroplanes.

PARIS, Nov. 28—News has been received from the front of Albert Guyot, one of the leading French race drivers, who will be remembered as a competitor for Delage in the last Indianapolis 500-mile race and the driver of a Sunbeam in the 1913 speed carnival at Indianapolis. Guyot is attached to the headquarters staff of one of the French army corps in the Argonne district, close to the German frontier. He is a member of the motor corps, with the rank of sergeant.

After having been in hospital a few days with a slight attack of dysentery, Guyot recovered and resumed duties. There is a general impression among those who have not been at the front that the men in the motor corps run less danger and display less bravery than those occupying the trenches or fighting in the open. In this connection Guyot mentions that persons holding this view should pay a visit to the firing line. "Only yesterday," he writes, "we lost 500 men in half an hour in what was considered a very successful attack on the enemy's lines. Two men who were with me were killed outright. I can only suppose that it is my luck which brought me through without a scratch.

"We realize that it is going to be a long job, and that it will be months before we get back to racing cars again—if ever we do get back. But we have plenty of determination and plenty of patience, and in the end we shall win all along the line."

Defends Battery-Coil Ignition

Claims More Uniform Spark, Better Acceleration and More Power Are Obtained at Slow Speeds

By H. E. Rice
Atwater Kent Mfg. Works

PHILADELPHIA, PA.—Editor THE AUTOMOBILE:—While it is far from the writer's wish to place the question of magneto vs. battery ignition on a controversial basis, he cannot feel that Dr. Cunningham's letter which appeared in THE AUTOMOBILE issue of December 3 is conclusive. If Dr. Cunningham is right, then many of the foremost automobile engineers in the country are wrong and ignition practice is sliding backward at a most startling rate.

Before making comment in detail upon Dr. Cunningham's statements, it might be well to reflect that every radical change in automobile engineering or other fields generally passes through varying changes of ridicule, skepticism and prejudice, especially when such a change is of considerable commercial or economic significance. It is surely true, however, that if the change or development in question is a beneficial one, it ultimately wins its own battle on merit despite antagonism and negative criticism.

For several years the so-called high-tension magneto was generally used for ignition purposes. There can be no question that it served efficiently within its natural limitations, but about 2 years ago, coincident with the rapid development in electric lighting and starting equipment, the movement toward battery ignition (retrogressive according to Dr. Cunningham) set in and at the present time over 50 per cent. of all cars costing from $500 to $2,500 have retrogressed (?) so far as to adopt it. Some have used it for several seasons and are apparently content to keep right on retrogressing with outputs which have increased yearly.

Let us consider the statements for which Dr. Cunningham is authority. First he questions: "Why the magneto"? Why, indeed!

Why should it be necessary for a car to carry a special little generator or magneto which generates a current for ignition purposes only and in the reverse order to which it is required, when we already have on the car a generator and battery which constitute a dependable source of current, having the best possible characteristics for ignition requirements?

In a well-designed ignition equipment the spark should be uniform throughout the entire speed range of the motor. The spark should be at least as hot and dependable on the first half turn of the starting motor as when the car is running at 40 miles per hour.

Its inability to furnish an adequate spark at very low speeds is of course the chief limitation of the magneto. Its spark heat at 40 to 60 r.p.m., ordinary cranking speeds, is very low, if indeed, it will furnish a spark at all. Even at 100 to 150 r.p.m., the magneto is not likely to furnish a spark sufficient for positive starting unless it is quite new and in the pink of condition.

When it is considered that in cold weather with a cold motor, the speed at which the average starting equipment will spin the motor is considerably less than the minimum speed at which the magneto will generate a dependable spark, one of the biggest reasons for the widespread adoption of battery ignition will be obvious.

Battery Best to Accelerate

In addition to the advantage of easy starting, any car equipped with battery ignition will throttle down and idle at a very much lower speed, with better accelerating qualities.

The only fair basis of comparison between battery and magneto ignition is to consider a magneto of the dual type in which a battery is used for starting and the current generated from the magneto for running.

Most of the manufacturers who have retained the magneto are using this dual type, which is at least as complicated as to circuits and mechanism as any standard battery ignition system. As opposed to the dual magneto system; a simple, standard battery ignition system is more simple, has fewer parts and less wiring, is more effective and is at least as dependable. It is also considerably less expensive in first cost and maintenance.

With reference to battery reliability, the amount of energy required by a properly designed battery ignition system is so small as to be negligible; with the result that if the battery is so far exhausted that the cranking motor will not crank, lights will burn down to a dim red and even the electric horn will refuse to respond, yet there will be sufficient energy to furnish ignition for many hundreds of miles and a normal hot starting spark will be available at the first quarter turn of the crank.

Many of the criticisms occasionally directed against the starting motor and battery are the direct result of undependable ignition at cranking speeds. The starting motor and battery are called upon to deliver a large amount of energy in proportion to their normal capacity for brief periods of time. It therefore makes a big difference in mechanical strain and wasted energy whether the engine starts on the first or second turn or only after 10 to 15 seconds of churning.

Regardless of the question of gas ionization and the relative speed of flame propagation from different kinds of spark, the magneto unquestionably gives a hot spark at normal speeds, and, therefore, ignition efficiency; also at high speeds the magneto produces a much hotter spark than in direct proportion—in fact, if the magneto is built and adjusted to give a sufficiently hot spark at very low speeds, it will be so hot at high speeds as to damage the plugs or contact points in the course of a short time.

Battery Spark Amply Hot

It is the contention of the manufacturers of the one or two standard battery ignition systems which have been widely adopted, that the spark produced by these systems is amply hot to do the work at all speeds, and as a matter of fact, no magneto has been able to show any increase in efficiency from either standpoint of power produced or gasoline consumed than a battery ignition system of the type now being used by many of our foremost car manufacturers.

As a matter of fact, a properly designed modern ignition equipment provided with automatic spark control will show an increase in power, flexibility, acceleration and gasoline economy over any magneto. Many manufacturers will testify to this fact.

Dr. Cunningham is in error relative to the necessity for constant spark lever manipulation required in order to use battery ignition properly. He has overlooked the very successful use of the automatic spark advance feature now coming into widespread use.

The results obtained by some of the car manufacturers using this device led them to discard altogether the use of the spark lever. The automatic spark advance also affords a factor of increased safety by automatically retarding the spark for starting. It contributes to the pleasure and ease of handling the car by leaving the timing of the spark entirely to the automatic feature.

For anything like equal efficiency a magneto equipped car requires not only a spark control lever, but its intelligent handling.

Battery System Simpler

The writer feels that Dr. Cunningham errs in intimating that the reliability and lasting qualities of a properly designed battery ignition device are not equal to those of a magneto. There is less mechanism and far less mechanical energy involved in a properly designed battery system than in a magneto, also the speed of the former is but one-half that of the latter, thus saving somewhat in bearing wear. The battery system may be installed in a far simpler and less expensive manner than the magneto, and if its installation is attended with a tenth of the thought and care usually given to the installation of a magneto, it will last as long as any other part of the motor.

With reference to the canvass made by Dr. Cunningham among chauffeurs driving cars equipped with battery ignition, no comment is necessary other than to express a sincere conviction that the men questioned did not represent a fair average of the sentiment which is, without question, rapidly growing in favor of battery ignition.

If Dr. Cunningham could have extended his inquiry to sales managers, engineers and superintendents of several of the larger car manufacturers who have successfully used battery ignition for the past two or three seasons, together with some 300,000 pleased owners of cars equipped with ignition of this type, he would possibly have led the readers of his communication to a more accurate conclusion.—H. E. Rice, Atwater Kent Mfg. Works.

90 Per Cent. Aluminum in Piston

An aluminum piston made in Belgium has been analyzed for *The Autocar* and shows that an ordinary alloy of this metal can give good results for piston work. The analysis is as follows:

Copper	6.8 per cent.
Zinc	2.44 per cent.
Iron	0.14 per cent.
Silicon	0.22 per cent.
Aluminum	90.40 per cent.

The specific gravity of the sample is 2.87.

93% of Kansas Cars Owned by Farmers

Topeka, Kan., Dec. 11—Checking the list of new automobile licenses shows that 93 per cent. of the cars in this state are bought by farmers. Those who have sold their wheat are buying cars and those who have not sold their wheat are giving chattel mortgages on their crops to buy cars. Thus far in the fiscal year 47,200 automobiles and motor trucks have been licensed in this state. There are several hundred of the commercial vehicles, but the bulk of the registrations are of family touring cars. Automobile licenses are being recorded at the rate of nearly 100 a day, continuing the average struck during September and October.

Measuring Efficiency Correctly

Promptly Detailed Information of What Is Done Each Day Compared to What Has Been Done and What Can Be Done Is Best Method —The Two Great Fallacies in Gauging Results

By H. L. Gantt

¶Editor's Note—The following article is a digest of a paper prepared by H. L. Gantt for presentation before the annual meeting of the American Society of Mechanical Engineers held in the Engineering Societies' Building, New York City, December 1-4.

TO the engineer the word "efficiency" has a definite meaning, which may be expressed approximately as the ratio of the useful result produced to the effort utilized in producing it. To the public in general it means simply doing things better.

It is very unfortunate that the term "efficiency engineer" was ever invented, for every engineer is engaged in the work of promoting efficiency, and it seems presumptuous for any class of engineers to arrogate to themselves a title which implies that they are pre-eminently promoters of efficiency. A more correct appellation would be "management" or "industrial" engineers.

Waiving the subject of name, however, it is certainly a fact that the agitation of the subjects of management and efficiency during the past few years has caused many employers to study their management problems very much more closely than heretofore, with the result that there has undoubtedly been a marked improvement in the efficiency with which industrial operations as a whole are being conducted.

So far so good. But in spite of this increase in efficiency, the greatest of our industrial problems, the relation between the employer and the employee, seems but little nearer solution. While there has been a distinct improvement in isolated cases, these cases are few compared with the total number.

Widening the Gap

It is safe to say then, that the promotion of efficiency is not alone sufficient to serve the needs of a nation that aspires to be a leader in industrialism. As a matter of fact one of the most efficiently run plants I have ever seen promises, unless my theories are all wrong, to widen the gap between employer and employee. The solution lies deeper, and before we can make any real progress toward it, we must revise some of our fundamental conceptions.

The present system of railroad accounting had been developed, and certain ratios accepted as measures of efficiency of operation; notably among them the ratio of operating expense to total income.

Being accustomed to having the managerial efficiency of railroads expressed by a simple ratio, the financier demanded a similar simple measure of the efficiency for an industrial plant. The cost accountant promptly gave him what he called the ratio of "non-productive" to "productive" labor, which he said should be low for good management. By "non-productive" labor he meant salaries of all kinds, and all other labor that could not be charged directly to an order, including miscellaneous labor such as watchmen, sweepers, truckmen, etc. By "productive" labor was meant simply that labor which could be charged directly to an order.

While the ratio of operating expense to total income may be a fair measure of efficiency in a transportation company, the ratio of "non-productive" to "productive" labor is not only not a fair measure of the efficiency of operation in a manufacturing plant, but is often exactly the reverse.

The Two Fallacies

To my mind the widespread use of this ratio as a measure of efficiency, has been more effective in producing inefficiency than any other single factor, except the oft-repeated statement that you must have low wages if you would have low costs. Until these two fallacies are absolutely discredited, we cannot expect a solution of our most serious problems.

Of these two fallacies, the second, namely, that you cannot have high wages and low costs, seems to be yielding gradually to the overwhelming mass of evidence against it. So many cases are now on record where the industrial engineer has increased output, raised wages, and at the same time lowered costs, that only those who are too conservative to investigate are still holding on to the old theory. Better still, many employers have shown the courage of their convictions by adopting a scheme of management for the increase of output and the reduction of costs, which they are perfectly well aware will make a decided increase in wages. With evidence of this kind at hand, it is safe to say that this fallacy will before long be entirely discredited. On the other hand it must be fully understood that something more than a simple increase in wages is necessary to increase output, and if nothing is done but to increase wages we are sure to get higher costs.

The other fallacy, that the ratio of "non-productive" to "productive" labor is a gauge of efficiency, is so firmly rooted, however, that it is hardly to be expected that it will yield in the near future.

In considering this subject I wish to call attention first to the terms "productive" and "non-productive" labor, which seem to me to be misleading. If any expense is "non-productive," namely, does not contribute to the end for which the factory was established, it should be eliminated. The salaries of the officers, foremen, janitors, truckmen, and laborers, as well as the money paid for taxes, insurance, or interest are necessary to the operation of the factory and therefore productive. They are, however, not chargeable usually to any specific order, but must be distributed over all the work done according to some definite rule. I prefer to call all such expenses that have to be distributed "indirect" expenses, and those that are chargeable to specific orders "direct" expenses. The ratio which we have in mind is thus more correctly described as that of "indirect" to "direct" labor. This, however, is a matter of names and does not affect the fact that to base any conclusions as to the efficiency with which factory is run on this ratio is misleading, and to attempt to use it as the gauge in operating a factory may be, and often is, productive of inefficiency rather than efficiency.

This fact can best be made clear by a series of examples. In a factory where this ratio was used as a guide the following incident occurred:

A foreman had ten men on a job, which he said could be done by eight if he could have a boy to supply them with work. He said, however, that if he made the change, the boy's wages would be called "non-productive" labor and his ratio would go up, with the result that he would be criticised, so he did not make it.

In the U. S. Navy an energetic officer studied the loading of ammunition and very much reduced the direct labor employed, but, being unable to reduce the indirect labor in the same proportion, the above ratio went up. He came in for very severe criticism, notwithstanding the fact that his total labor had been decidedly reduced.

I might give numerous examples of this kind, including one where two men took the place of sixteen, and a daily direct wage of $8 took the place of $48, with but little increase of the corresponding indirect expense. The result of this and other changes was that the ratio for that shop became over double its former value, with a marked reduction in the total cost. Needless to say, that the ratio theory in that plan is not regarded wih the same reverence that it once was. In plants where such results have been accomplished, those who have been accustomed to worshipping this ratio, at once demand another idol in place of the one that has been so badly discredited.

The Shattered Idol

Inasmuch, however, as the efficiency of the operation of a factory is made up of the efficiency of a great many independent operations, and is really indicated only by the cost of the various articles produced, there has not yet been found any easy way of indicating the efficiency without first getting the cost of the individual articles. Hence there is no readily available idol that can be substituted for the discredited one. Having been accustomed to an idol, however, both the accountant and the financier demand one, and are loath to give up the idol they have so long worshipped no matter how badly shattered it may be.

Detail Knowledge Essential

In speaking of the cost systems, we must discriminate between cost systems and expense systems. Before we can get correct costs we must have a correct knowledge in detail of all the expenses of a plant, and some idea of how to combine these to get costs.

In discussing this subject, I wish to avoid the controversy as to the proper method of distribution of indirect labor and indirect expense and to confine myself to the problem of how to get a true knowledge of the various items of labor and expense, both direct and indirect. This subject seems to have been given but scant consideration by the average accountant, who has usually assumed this to be easy and devoted his energies to working out elaborate theories as to what should be done with the various items of expense. Inasmuch as I find that the information which the office gets of what the shop has done is, as a rule, not very reliable, I feel that it is far more important to get this information correct than to get up elaborate schemes for using it.

Everybody is agreed that all expense of material or labor that can be readily charged to an order should be so charged, but whether the indirect labor and expense should be charged in proportion to direct labor or machine hours, and how other items of rent, taxes, insurance, etc., should be distributed, are questions which it seems to me should be largely determined in each case on its merits. I have never yet seen any general scheme that seemed to suit all cases.

A Reliable Cost System

We shall therefore confine ourselves to the consideration of what the essential elements of a reliable cost system are, and how to get an exact knowledge of them. These elements are a knowledge each day of

(a) What was done the day before.
(b) Who did it, and
(c) What was paid for it.

It is necessary to check these items daily, for it is impossible to check them accurately after the lapse of any appreciable time.

It is comparatively easy to get a set of returns purporting to give the above information, but the real difficulty comes in knowing whether these returns are correct or not. The only sure way of knowing whether these returns are correct or not is to know beforehand

(a) what should be done the next day
(b) who should do it, and
(c) what should be paid for it.

When we have arrived at a condition under which we can plan our work in advance on these lines, we have the basis of a real system of management, in which we can promptly check what has been done with what should have been done, and know with certainty each day how we stand.

When it is realized that the installation of such a system seldom results in an increase of output of less than 25 per cent., and often as much as 100 per cent., it is easy to see that the additional clerical work cuts but little figure. As a matter of fact *the clerical work needed to operate the best systems of this type is decidedly less than that needed to operate any of the standard cost systems put in by chartered accountants.*

It must be borne in mind, however, that during the process of installing the new system and training the employees to operate under it, the old system must be continued; and not until each function performed by the old has been taken over by the new can we drop the old entirely.

During the process of installation, therefore, we must to a large extent operate two systems. This necessarily runs up the ratio of "non-productive" to "productive" expenses, and the accountant lifts up his hands in horror at the expense the new system is running them into. If at the same time the new system is successful in reducing the "productive" labor, the ratio is still higher, and the "showing" is still worse, even though the total cost is less. I therefore repeat that the first step to be taken before introducing a modern system of management is to eliminate the ratio of "non-productive" to "productive" labor as a measure of efficiency.

The elimination of this ratio as a measure, and the establishment of the fact that total cost is the only reliable guide, will do much to pave the way for an improved system of management.

Its Functions

The first step is to revise our ideas as to the functions of a cost system. In the past the principal function of a cost system, besides indicating a limiting selling price, has been to enable those in financial control to criticise those operating the factory. These criticisms are usually from one to three months late, and are so general in their character as to afford, as a rule, no guide whatever by which the superintendent can be governed. Such a system is too often most highly prized for its worst defect, namely, that it enables those in financial authority to criticise without taking any responsibility whatever for showing how to do better.

If, instead of making the function just described the prime one, we raise to equality with it a function which requires the system to furnish promptly, day by day if necessary, exact information of what has been done and what the expenditure has been, we shall find that its most valuable function becomes, not finding costs, but furnishing the superintendent with information which helps him to reduce costs.

The Cost Accountant

In other words, before we can expect to get any great benefits from the newer managerial ideas, we must readjust our ideas of the functions of the cost accountant, *who must become the servant of the operating executive as well as of the financial executive.*

As long as the cost accountant is simply a critic, he may be called "non-productive," but when he furnishes the superintendent with prompt information which enables him to reduce costs he becomes "productive." Promptly detailed information of what is being done each day, furnished in such manner as to be readily compared with what has been done, and what can be done, is the best method of measuring efficiency.

Gray & Davis Variable-Speed Generator

New Method of Voltage Regulation—Change in Shape of Machines—Instruments Lighter—Refined in Detail—Two Motors and Two Generators in Line—All of 6-Volt Type

TWO starting motors and two lighting generators with many new features will constitute the Gray & Davis line for 1915. The most important change is that found in the lighting generators which are now of the variable speed type. Both generators and motors have been reduced in size, the accessibility improved and detail mechanical and electrical changes made in both systems.

The two types of lighting generators are the T rated to give a current output of 10 amperes at 6.5 volts and 1,000 revolutions per minute and the S which gives 10 amperes at 6.5 volts and 650 revolutions per minute.

The two starting motors are the Y and the H-1, the former being new.

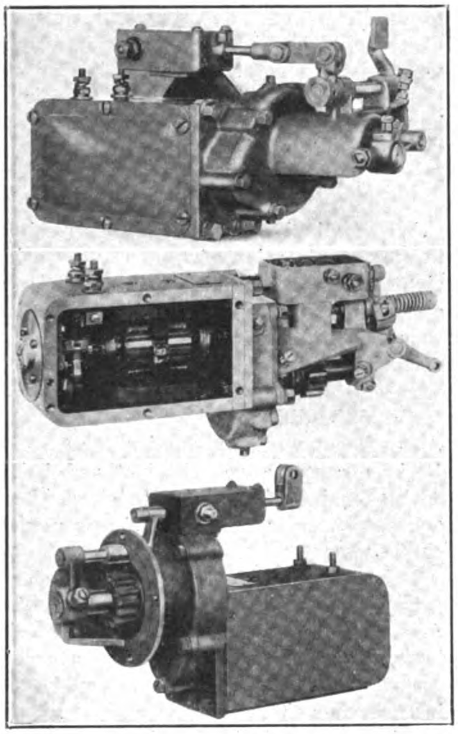
Most important of the changes in the generator is the method of voltage regulation. In the machines of this year voltage regulation was accomplished by maintaining the speed of the armature constant by the use of a centrifugal governor. In the new machine there is a combined regulator and cutout which rests on the top of the generator and which not only maintains the voltage constant regardless of speed variation but also breaks the circuit when the speed of the generator drops so low that the voltage it generates is less than that of the battery.

Rectangular Frame

The new machines have a rectangular or magnet-shaped frame which is constructed of one flat piece of low carbon steel formed into a U shape. This change in frame construction gives greater ruggedness, is more compact, allows more accurate alignment of the bearings and the number of parts is materially reduced. Magnetic leakage is also avoided.

The type T generator gives a 6.5-volt, 10-ampere current at 1,000 revolutions per minute, is intended for four-cylinder cars and is designed to run at approximately two and one-half times crankshaft speed, or in short, to be driven at its rated speed at a car speed of about 10 miles per hour car on high gear.

The type S generator is for six-cylinder machines and is to be driven directly from the magneto shaft, at one and one-half crankshaft speed. This gearing allows the generator to run at its rated speed of 650 revolutions per minute when the car is driven 10 to 12 miles per hour.



Upper—Y motor designed for open flywheel installation. The starting switch is on top. Middle—Y motor for open flywheel installation but with starting box at one side Lower—Y motor enclosed flywheel type

The generators for 1915 are similar in appearance to the type Y starting motor, being of the longitudinal yoke design. This construction has enabled the production of the same current at the same speed as heretofore but with a smaller and lighter machine.

The type T generator complete with regulator cutout weighs 20.5 pounds, a reduction of 6.5 pounds. It measures 4.13 by 5.34 by 8.62 inches, while the G-1 generator which it replaces measures 5.5 by 6 by 11.67 inches.

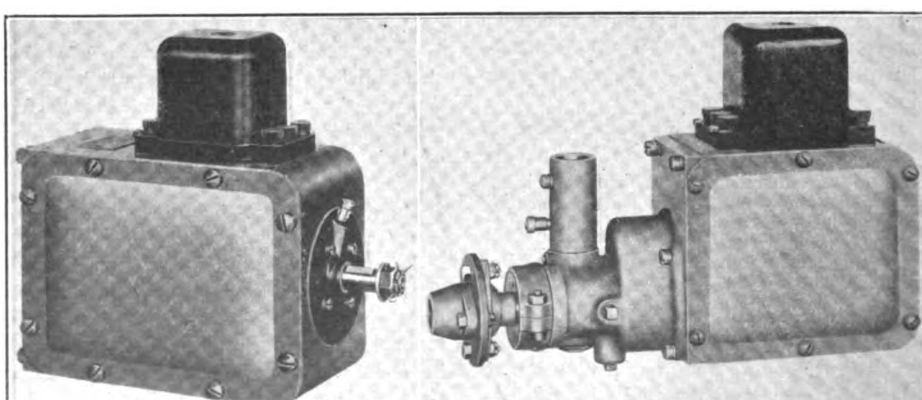
Likewise the new type S generator which takes the place of the type E has been reduced 1.25 pounds in weight and the dimensions reduced from 5.5 by 6 by 12.5, to 4.63 by 5.97 by 10.75 inches.

The type Y starting motor will be standard equipment for all except the largest cars. This motor is a new design and is rated at 6 volts, 100 amperes at 2,800 revolutions per minute. Cars with motors of extreme size will use the type H-1 motor, which was a standard model this year. It carries its full load when operating at 1,500 revolutions per minute, at which time it draws a current of 150 amperes. It operates only on the 6-volt circuit.

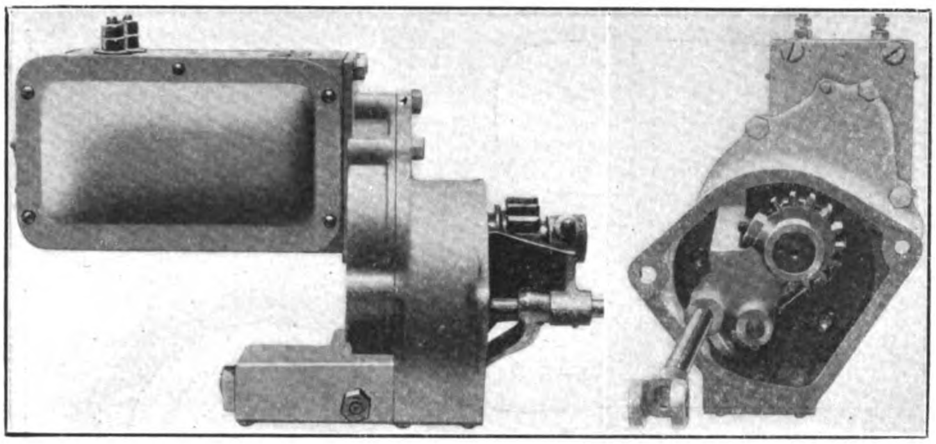
Accessibility Improved

Mechanical improvements in the starting motor have been directly chiefly towards accessibility and ease of inspection of parts and to the refinement of details to give greater strength. For accessibility, the new Y motor has the longitudinal type of field yokes which readily permits access to the interior of the motor by the removal of the cover plate from the side. The entire interior mechanism of the motor can be reached by removing these side cover plates by taking out six screws.

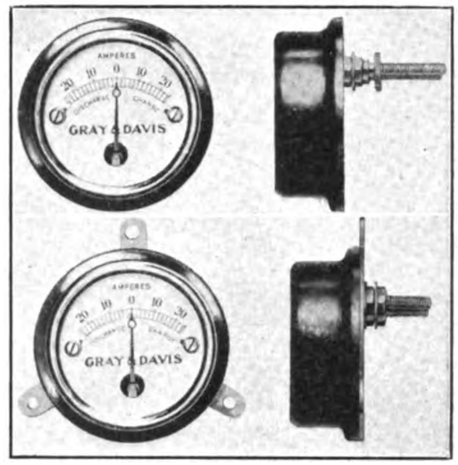
Electrical improvements in the Y motor have given it better torque than the type K motor of this year and it



Left—Model S generator with regulator cutout placed on the top. Right—Same dynamo with geared head and vertical ignition drive



Two views of Y motor enclosed flywheel type with side mounting of the switch. The driving gear construction is shown in the end view



Ammeters of the stud and case supported type

weighs only two-thirds as much, the new motor weighing 19.75 pounds and the old one 31 pounds. While the type K motor was rated to develop normal load at 3,600 revolutions per minute with a current draw of 100 amperes, the type Y develops the same torque with the same current consumption at 2,800 revolutions per minute. The type Y motor is 4.312 by 4.72 by 8.16 inches. These dimensions compare favorably with the K motor which was 5.75 inches in diameter and 8.875 inches long.

For 1915 the flywheel drive will be standard. The speed reducing gears and starting switches are integral with the motor casing and arranged so that a single movement of the starting pedal simultaneously meshes the sliding pinion with the flywheel gear and closes the starting switch.

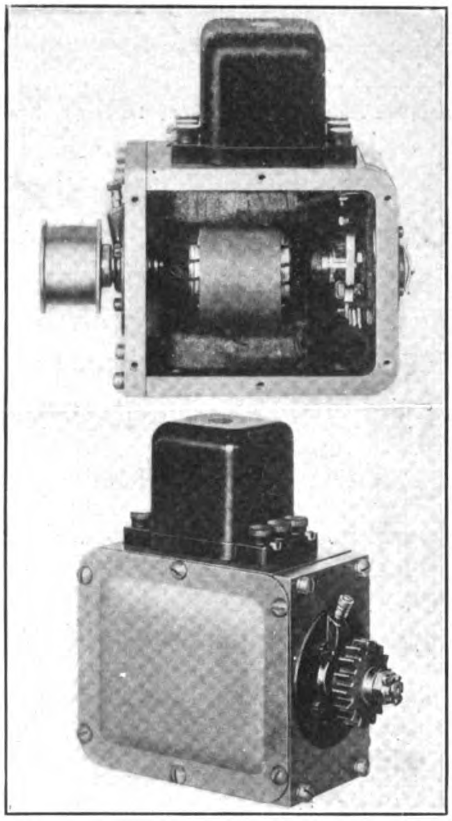
Cranking Speeds

Cranking speeds vary according to the motor but the following table showing the speeds of various sizes of motors will give an idea:

Number of Cylinders	Bore	Stroke	Cranking Speed
4	2.87	4	210
4	3.5	5	132
4	3.75	5	124
4	4.12	4.5	135
6	3.38	5	108
6	3.75	5.5	104

Under normal conditions the draw on the battery varies from 65 to 110 amperes. Under adverse conditions such as a cold motor and a chilled battery the initial kick may be as high as two and one-half times the normal running current but this maximum draft is only for a fraction of a second.

In all Gray & Davis systems the starting and lighting machines are separate units although in the special system recently brought out for Ford cars these two are mounted one above the other in a single case. Only 6-volt systems are built and the single wire is standard construction.



Upper—Type T generator with armature and fields exposed by removing the side cover
Lower—Gear-driven generator. Note oil hole just above gear and general accessible construction

Recent Court Decisions—No Garage in Park

In an interesting case recently decided in Oregon, it was held that the park commissioners of Portland did not have the right to build a garage to house cars which were used by the park commissioners and park employees in a part of the park adjacent to the street.

Landowner Plaintiff

Suit was started by a landowner who owned property across the street from the park to procure an injunction against the commissioners on the claim that they were diverting part of the pleasure grounds for unauthorized purposes. The City of Portland has secured the park's site in the year 1871 and in the year 1909 the ground opposite it had been purchased by the party bringing the suit.

Court Ruling

The Court held that the park commissioners did not have the right to make excavations preparatory to building a garage for the storage of automobiles and motor trucks to be used by members of the park board and other employees, as the park was to be used exclusively for pleasure purposes and accordingly issued an injunction against the board.—*Messinger vs. Mische*, 142 *Pacific* (*Oregon*) 612.

Coupé Bodies for Runabout Use

Suggested Designs for Tops Which May Be Applied Directly to Runabout Without Necessitating Material Changes—Ordinary Top Irons Are Utilized

By George J. Mercer

THERE is considerable activity in the body shops converting runabouts and touring cars into closed bodies by the addition of an upper structure that can be easily removed when the warm weather returns. At present nearly all the changes made are by the addition of tops that make the body into a coupé or limousine. The falling type of top, like the landaulet, is not in fashion for this quick change. Some body builders are equipped with parts already made up for certain makes of cars, and are prepared to assemble same and get the car out at short notice. This will make the price to the buyer an interesting figure, because the parts are made in quantities. Nevertheless individual designs will be required to a large extent, and to illustrate this, two makes of popular cars are shown with tops for changing the runabout into a coupé.

Ordinary Top Irons Used

A 1914 Cadillac factory model is shown in Fig. 1; it must be taken into consideration, that, when this top is made that it is founded on the essential that the parts added can be removed when warm weather returns and the original features restored without showing any defacement of the painted surface. Hence in assembling the top on the car, the regular top iron sockets on the body are utilized for attaching the top at the sides and rear corners. The framework of the top is made to fit over and come flush with the under side of the socket, completely covering it, and a stud is let into the framework and fastened with a nut at the bottom. These sockets provide four fastenings and take care of the sides and back. At the front, the sockets for the windshield are used in similar manner to receive studs set into the front posts.

New doors are made, the hinge line on the old doors preventing their use, as it will not line up with the hinges on the upper part. The lock handle must run through to the outside, and as before mentioned it is the intention to leave the door of the runabout without changes so that it can be reassembled.

The upper structure is made to offset outside the body line so as to cover the socket irons, and the miniature front and back views show this offset line continued across the doors. Looking at the side view again, it will be noted that the offset belt line is continued forward and rounded up until it forms the door line at the front post. This will make the upper part of the door wider than the lower part, the reason for this being that the door line is established in the body and the front post is established by the bearing for the windshield. In order to have the door meet the post without having wide framing that will obstruct the vision, the door is made in this manner. The original shape of the cowl is indicated by dotted lines and where the door overlaps the cowl it is free from contact with the painted surface and the trimming inside the door will serve as a windbreak. The lower part of the door will fit into the regular door opening and special hinges are made to allow of their use at the old hinge plates without cutting the pillar.

Regular Windshield Utilized

Doors made in this way will not permit of the glass being lowered, or at most not over 2 inches. The side and rear glasses are also stationary but the front is made with the regular windshield, the upper part a visor and the lower to swing for ventilation.

A rounded top for this design will add to the cost of manufacture. Aluminum panels are used throughout, on the sides, back and roof, the metal being joined as far up on the roof as the width of the sheets will permit. The ends are well fastened with wood screws and then soldered, while the metal is also turned under on the lower edge and into the window openings. The absence of moldings and the extreme rounded effect is decided by the intention to make the upper part conform to the original body lines. The framing is of wood, and this is made as light as possible, not only to save weight but to diminish the offset of the top from the body lines as much as the conditions will permit.

Frameless Glass Windows

The size of the body will govern the size of the top framing, because it fits over and outside the body, the height being determined by proper headroom over the seat cushion. The windows are frameless glass with natural wood garnish inside and the most suitable trimming is a dark cord cloth that will look well with the leather finish of the seat and cushion. This trimming will be finished smooth and will cover the sides, back and roof and one dome light is placed in the center of the top.

Fig. 2 is a design of top fitted to an Overland runabout, the lines are different from Fig. 1, but they are more suitable for the straight lines of this body. It is fastened in the same manner as the previous design and the front framework rests on the bearing previously occupied by the windshield. In this design a bent corner glass is used to piece out the space between the door and the front post and this bent glass corner is equally applicable to the design in Fig. 1.

The construction of this top is less expensive than Fig. 1. The top is covered with canvas over wood bows, the cloth ends being fastened under the drip moulding that runs all round the top. The back and rear side panels are one piece of aluminum which is fastened at the top under the drip molding and under the molding around the window openings and at the bottom it is turned under and fastened with screws to the bottom edge of the framework, the door panels and the narrow belt panels are also aluminum and the posts of wood. The door window is made to drop about 12 inches, the rest of the windows being stationary except the front windshield; all the windows are frameless glass and the door glass is supported with a lift strap. Wood with natural finish is used inside on the window edges and the same applies for the trimming and the dome light as for the design in Fig. 1. The miniature end views complete the illustrations sufficiently to convey the appearance of the design from the several veiwpoints, and the same rules for proportions apply as before mentioned. The accompanying scale in feet and inches will permit any desired measurement being obtained on the larger illustrations and the miniature views are made just one half the size of the large drawings.

The cost of a top like either of these designs will be governed by the workmanship, material used and the reputation of the maker. Such tops are often made at a middle figure of $200.

Hints for Closed Car Trimmings

On the doors there should be large pockets covered with a flap and the tufted trimming line can be carried across the door above the pocket. At the bottom of the door the carpet will run up to the pocket and will match the material in shade and the silk curtains on the doors, rear side windows and the back will also harmonize. If possible, the door curtain should not be fastened to the door itself but on the toprail above the door, thus avoiding possible staining of the curtains by the rain when the door is opened.

The doors should have inside handles and sensible hinges and locks. There is a toilet case on each side of the car just back of the door and additional appointments may be added to suit the tastes of the customer, but there is not space to place much more than here specified.

The trimming designs of closed bodies at present aim to give as soft a cushion and back as possible. Fewer buttons are used and the small biscuit and the pipe-and-point are seldom found on the new cars. The superseded designs no doubt kept the trimming in good order much longer, but the present effort is to secure the same soft effect in a new job as was formerly found only in a body that had seen service.

Harmonious Color Schemes

Color designs seem to be definitely settled to the rich sober hues that are modest and show refined taste. It is a rare thing now to see a closed body painted other than the conventional dark colors. This tends to make the cars look alike and it allows a design of real worth to stand on its merit. A conspicuous color will often attract the attention of the customer and bias the judgment, but where a sober, harmonious color scheme prevails on the several body styles, a customer's attention is not diverted from those essential features that they have predetermined are necessary.

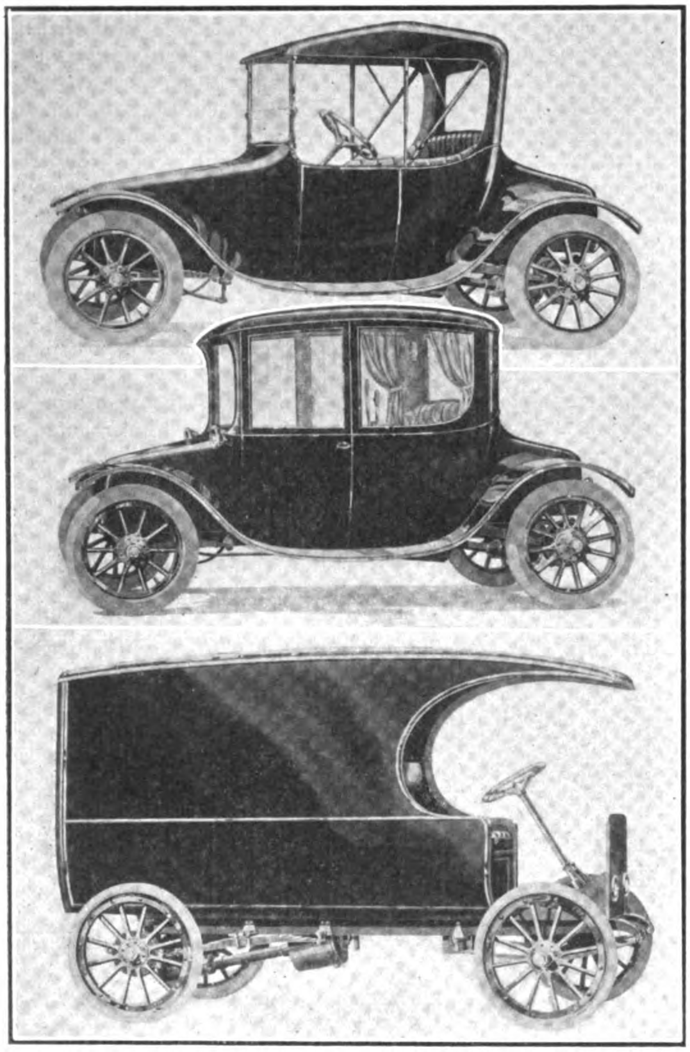
Milburn Electrics in Three Models

Line Consists of Coupé, Roadster and Delivery Wagon —Light But Strong Construction a Feature—Worm Gear Drive—Mileage Obtained 50 to 75 Per Charge



Upper—Milburn electric roadster which, fitted with seventeen-plate twenty-cell batteries and capable of about 70 miles per charge, sells for $1,285

Middle—Coupé type, which has twenty-cell, fifteen-plate batteries and travels 60 to 70 miles on a charge. It lists at $1,485

Lower—750-pound delivery wagon, the chassis of which is priced at $985. Bodies of all types are $100 and upward

THE Milburn Wagon Co., Toledo, O., long established in the vehicle-making business and a large producer of bodies for the automobile trade in general, has placed upon the market the electric vehicle with which it has been experimenting for the past 2 years. The car appears in three models—a coupé at $1,485, a roadster at $1,285 and a delivery wagon at $985. Not only does the concern bring the electric down into the comparatively low-priced field, but the construction is lighter than that generally applied to the design of electrics.

All three models have practically the same specifications, although the wheelbase of the delivery is 90 inches, whereas that of the passenger types is 100 inches. Motors and controllers are of General Electric make and batteries of Philadelphia, twenty-cell type. Cantilever springs suspend the passenger chassis, while the delivery uses semi-elliptics in front with cantilever rears. There are four forward speeds provided, and tires on the roadster and coupé are 30 by 3 1-2 pneumatics. The roadster has the greatest mileage per charge, it being capable of 60 to 75 miles, it is said. The coupé will run as far as 70, and the delivery as much as 50 miles on a charge. Worm gear axle drive is employed.

The coupé body is very graceful, with long stream lines, and although it is somewhat smaller than the conventional heavier one found on most electrics, it provides ample accommodations for four persons. Large doors, 28 inches wide, and sashless glass windows add to the attractive exterior, which is painted a dark blue. The interior is commendably well appointed, containing the complete equipment found in inclosed bodies of the highest type. The upholstery is of French fabric specially made for the car. Mechanical window lifters are fitted to both doors and to front and rear windows.

Low Center of Gravity

The body is hung low on the cantilever springs. This low center of gravity provides a factor of safety against the possibility of upsetting or skidding. The manufacturer states that preliminary tests have shown the reduced weight of the Milburn makes it very easy to control in crowded traffic.

The coupé weighs approximately a ton, and with its battery of twenty cells, it attains a normal speed of 17 miles per hour and a maximum of 20. It has a mileage ranging from 60 to 75 on a charge, the rated amount of which is 180 ampere-hours.

The motor is of high speed special design, and the controller is a continuous-torque, non-arcing, drum type which gives four forward speeds and two reverse. Both speed control and steering are by horizontal levers.

The front axle is fitted with Bower roller bearings, while the rear axle, which is of three-quarter floating type, employs Hyatt heavy-duty roller bearings. Its shafts are of chrome-vanadium steel. The drive is direct worm type with no universal joints, and is carried on Hess Bright ball bearings.

The full cantilever spring units are of chrome-vanadium steel, self-lubricating. Twelve-inch, Thermoid-lined brakes are on each rear hub, and the construction is such that none of the braking strains is taken through the worm drive of the motor.

Alarm Prevents Power Waste

A feature which is calculated to eliminate unnecessary waste of power is an automatic alarm which rings if the brakes happen to be applied while the power is on.

The roadster has the same specifications as the coupé, only it is about 100 pounds lighter. This less weight together with its 25 ampere-hours more battery capacity due to the cells being of seventeen plates instead of fifteen as in the coupé, give the roadster a mileage of approximately 70 under normal driving conditions. The normal speed is 19 miles an hour with a maximum of 24.

Instead of having lever steering, the roadster is fitted with a 16-inch steering wheel connecting with a worm-and-nut type of steering gear. Distinctive appearance is given it by the use of a rain-vision windshield and a special one-support top.

Delivery Car Capacity 750 Pounds

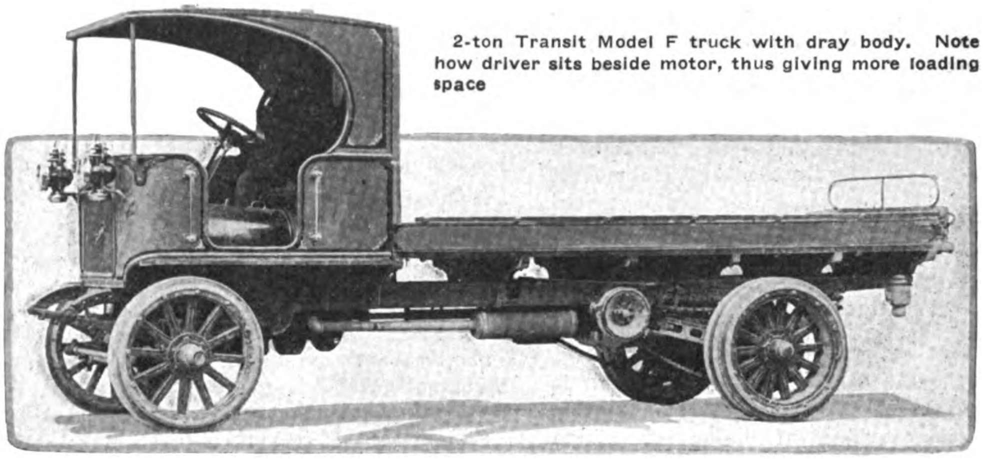
The delivery machine, with a 90-inch wheelbase, has a carrying capacity of 750 pounds in addition to the operator and one passenger. The price of $985 covers the chassis only, due to the wide variety of body types required for various conditions of service. Bodies of all forms are furnished at prices ranging from $100 upward, the styles being determined by the use for which the vehicles are intended.

This commercial car has a battery capacity of 180 ampere-hours also, and a normal speed of 14 miles an hour with a limit of 17. It will run from 40 to 50 miles on a fully charged battery.

The equipment of all the models is complete, consisting of two 6-inch front lamps, tail lamp, two inside corner lamps in the coupé, bell voltmeter, speedometer, 8-day clock, tire pump, hydrometer, jack, tools, and so on. Although the 30 by 3 1-2 tires included in the standard equipment are Goodyear special electric pneumatics, Motz cushion tires may be had optionally at an extra charge, these being of 32 by 3 1-2-inch size. The delivery car is equipped with 32 by 3-inch solids, made specially for electrics.

Four Chassis for Transit Trucks

Models Vary from 1 to 5-Ton Types—Two-Thirds of Payload Is Carried on Rear Wheels



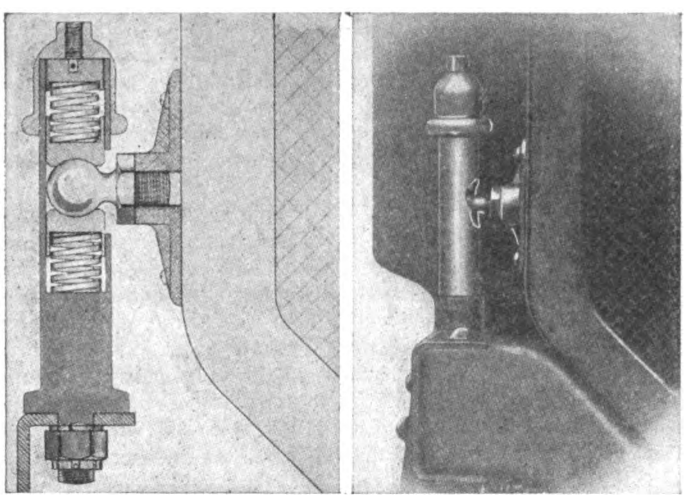
2-ton Transit Model F truck with dray body. Note how driver sits beside motor, thus giving more loading space

THE Transit Motor Truck Co., of Louisville, Ky., which is entering upon its fourth year of active manufacture, offers Transit trucks for 1915 in four models, of the following capacities:

Model E, 1-ton, $2,000; Model F, 2-ton, $2,850; Model T, 3.5-ton, $3,500; Model V, 5-ton, $4,500. The prices are for the chassis only, and bodies of any style desired are furnished at additional prices depending upon style and size.

Driver's Cab a Feature

A new feature of the Transit truck is the design of the driver's cab which not only renders the motor more accessible but affords greater loading space and better load distribution than is found with trucks having a hood over the motor and the driver's seat placed back of the motor. In this design the driver's cab is built the width of the body and arranged so that the driver sits on one side of the motor while the helper sits on the other, the motor being covered by a sheet metal hood between the seats. By this construction a loading space of 3 to 4 feet is gained which means that for a given length of loading space the wheelbase may be made proportionately shorter and the amount of overhang of the body back of the rear axle is reduced. The proportion of all Transit trucks is such that two-thirds of the payload is carried on the rear wheels.



Left—Detail of radiator mounting used on Transit trucks. Right—External view. This ball-and-socket spring suspension provides a universal action protecting the radiator from torsional strains

All models are built on the same general design and the following equipment and specifications apply to all models alike: The Continental motor equipped with Mea magneto and Rayfield carbureters is used in all models. The clutch is the Hele-Shaw universal type. Timken front and rear axles and jackshaft are used, the latter carrying a selective type gearset with Timken roller bearings throughout and having three speeds forward. All models are chain driven. The frames are of pressed steel of the fish-belly type.

Three-Point Suspension

The motor is mounted on a sub-frame having three-point suspension and the drive from the motor to the jackshaft is through a straight shaft fitted with two universal joints.

The Ross steering gear is mounted on the right side as are also the control levers. Semi-elliptic springs are used all around and in addition to these a coil bumper spring is used with the front and a cross supplementary spring in combination with the rear springs, this cross spring coming into action only when the truck is loaded.

The 1-ton is offered with a wheelbase of 120 inches to 144 inches; 2-ton, 132 inches to 144 inches; 3.5-ton, 144 inches; 5-ton, 144 inches to 156 inches.

Business Gain in Western Canada

Trade Is in Best Condition for 3 Years, Despite European War—Farmers Buying Cars—Agencies in Demand—Sales Plentiful—Truck Field Developing

By A. C. Emmett

WINNIPEG, MAN., Dec. 10—In spite of the European war, the automobile trade in western Canada is in a better condition at the present time than it has been for the past 3 years.

A general review of the trade reveals the fact that the dealers are all doing a good business and in some cases such as the Ford, Studebaker, Hupmobile, Overland and cars of the medium-priced class their sales records show that business for the month of November was from 35 to 50 per cent. in advance of the record for the same period in 1913.

Horses to War

A great deal of this improvement is due to the heavy buying by farmers, who, in the provinces of Saskatchewan and Manitoba, have exhibited a tendency to replace their teams with a light car and sell their horses to the British war department for remount purposes. The trade in the cities is, however, still of a good class and quite a number of high grade cars have been sold in the cities of Winnipeg, Brandon, Regina and Edmonton.

Traveling representatives of the firms who act as factory distributors for American manufacturers, send in optimistic reports from every part of the three provinces and accompany the reports with signed contracts covering 1915 business and orders for the immediate shipments of demonstrating cars.

The phenomenal fall weather, which has been enjoyed throughout October and November, has had the effect of keeping cars in use for a much longer period than is generally the case and it has been interesting to note the number of country buyers who have come into the city and taken delivery of their new cars and started for home by road. One day in particular, November 18, no fewer than seventeen new owners started from various hotels in this city driving new cars to points widely apart in the province of Manitoba.

Good for 1915

Manufacturers' representatives who have visited Winnipeg with a view to looking over the territory for agency purposes have been surprised at the demand which they have found existing and have advised their factories to send forward shipments promptly and take care of the needs of agents in the future as in their opinion Western Canada will be a good market for cars throughout the whole of 1915.

Developing Truck Business

Another phase of the situation which is receiving the serious attention of the trade are the possibilities that exist for the opening up of good business in the motor truck field with trucks of 1 and 2 ton capacity for use by farmers. An educative campaign in this respect was discussed at the last meeting of the Winnipeg Motor Trades Association and a committee was appointed to go thoroughly into the matter and report for the benefit of members at the next general meeting.

That dealers are making no sales that are not founded on the best business policy under existing war conditions is proved by the fact that no second-hand cars are taken in part payment of a new car until such time as a buyer is found for the second-hand car at a price mutually agreed upon between the dealer and the purchaser of the new car. This arrangement has led to a little extra effort on the part of the dealer to locate buyers and secure business in a new car and territory which was considered unpromising for the sale of new cars at the present time has been found a good market for the second-hand car and over 100 of these cars have been sold.

Farmers Buy

As THE AUTOMOBILE representative I have traveled a great deal in Manitoba and on every hand has been found evidence of the desire to purchase a car either for the sake of its utility in the life of the farm or simply for the added opportunities it provides for social intercourse. This desire coupled with the fact that farmers were able to sell quite a number of horses to the British government has been responsible for the sale of a number of cars sooner than otherwise would have been the case and the dealers are consequently in a better condition as far as winter trade is concerned than they have ever been before.

At the commencement of the war it was anticipated by the pessimistic brigade that the business of the automobile dealers would come to an absolute standstill and this opinion was shared to a very great extent by a number of influential business men but those who were in actual touch with the motor industry saw the signs of good business and with commendable foresight closed out big contracts with the manufacturers for immediate delivery so that when the combination of good weather and high prices for wheat placed the farmer in a good position and brought him into the market for a car they were ready to give him immediate delivery and close sales which might not have been secured at a later date.

Medium Cars Sell

Ford sales are of course not to be wondered at but take as a basis for demand the sales made by the Winnipeg distributing branch of the Ford company during the month of November are nothing short of phenomenal and would lead one to the conclusion that all the buyers were out to get a car that would be low in cost and cheap to operate. That this was not the case was soon evident by reports from the Overland, Studebaker, McLaughlin-Buick and Hupmobile agents. All these reports were of the most optimistic character and backed up their statements by the addition of the names of those to whom the cars were sold and the names of those who had applied and signed agency contracts for sub agencies during 1915.

As all these contracts are based on the sale of three cars before an agency contract is given it will be readily seen that the outlook for business in western Canada as far as the three provinces of Manitoba, Saskatchewan and Alberta are concerned is extremely good and when the total sales are figured at the end of the 1915 season it will be found that the business has been equal to the best year that the dealers of Western Canada have ever had.

Latest statistics issued by the municipal commissioner for the province of

Manitoba show the total of cars owned in this province as 7,340 at the end of September, 1914, an increase of over 1,200 cars during the past year.

Turning from the car sales to the accessory and tire trade, which form a barometer for conditions in the use of cars already owned, it would seem that there is no falling off in business on this side of the trade as in the case of the tire concerns the reply to a query as to conditions that are likely to obtain during 1915 brings the answer that conditions were never better. Orders on hand are in excess of business at the same time last year and judging by the consignments of tires ordered forward for spring delivery there is none of the owners of cars in the province who will not be making use of them next year.

The accessory dealers are finding business also equal to other years and are sending forward good supplies of material to country garages who are overhauling cars and getting them in shape for next year's work.

"Business as Usual"

Fancy stories of conditions in Canada since the outbreak of the war have been circulated in some irresponsible papers in the United States, such as: "Automobile owners in Winnipeg and Manitoba are using their automobiles with ropes on the wheels in place of tires as the war has made them so hard up they cannot buy tires." One factory representative actually arrived in Winnipeg from the headquarters of a big tire factory with the idea in his head that this was true and was more than surprised to find, "Business as Usual," the slogan of everybody with whom he came in contact. The gospel of hard times cannot be preached very successfully in western Canada just now and if there is anyone suffering from the war there are others who are ready and willing to tide them over the hard spot and keep the family together whilst they help the Motherland to fight her battles by sending forward men and supplies as fast as they are called for.

With this condition of things the automobile manufacturer need not be scared away from the Canadian market but should rather lay his plans to secure a share of the ever increasing business that will come with the development of western Canada when the war ends.

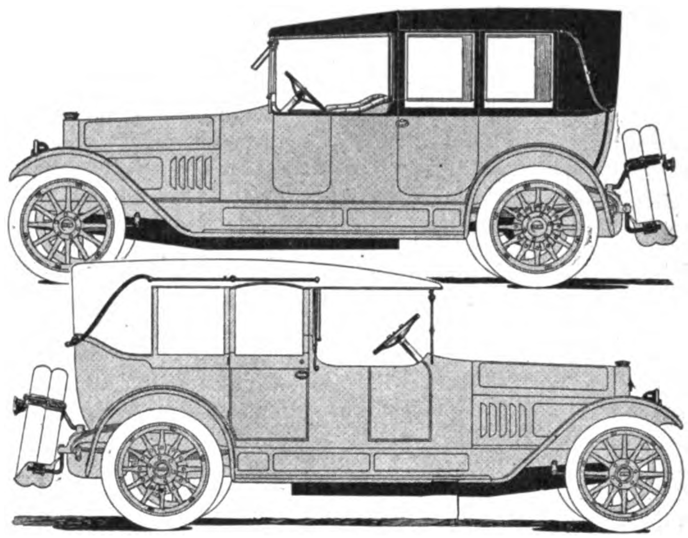
Some New Locomobile Special Bodies

SEVERAL bodies of more than usual elegance are on view at the New York City sales room of the Locomobile Co. of America. This private exhibition held there marks the inauguration of a special department for the planning and ordering of specially designed bodies.

Two of these new models are imported and three are made in this country. A handsome example of the French body worker's art is shown in the coupé built by Henry Binder, Paris, and mounted on a 38 chassis. It sells for $6,600. The other French design is a phaeton-landaulet by Bail Jeune Frères, Paris, and placed on a 48 chassis. This model lists at $7,500. The top and sides fold down so that the car can quickly be converted into an open model.

The American bodies are of Holbrook make, a landaulet-limousine on a 38 chassis selling for $6,150 a coupé-landaulet at the same price and a semi-touring car placed on a 48 chassis and listing at $6,800. The latter equals in utility the phaeton-landaulet mentioned above, as it can be used as a closed or open car as desired.

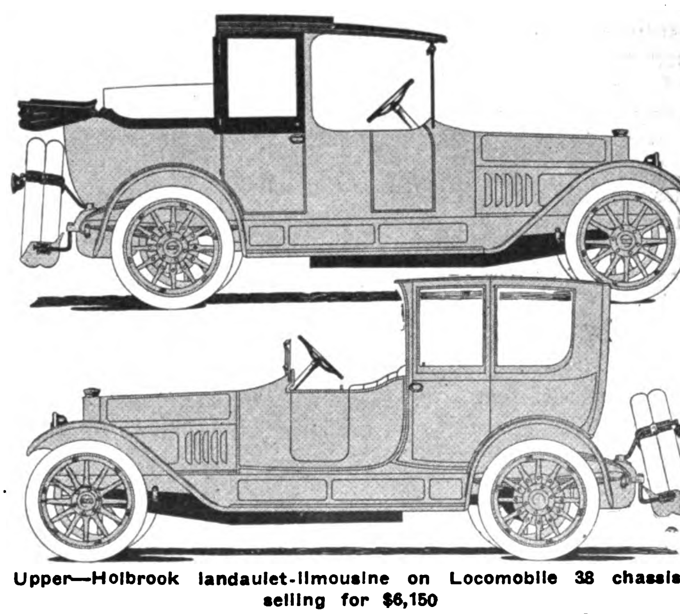
This new department, as announced in THE AUTOMOBILE for October 8, is managed by J. Frank de Causse, who has been connected, as assistant manager, with Kellner & ses Fils, and it is planned to furnish patrons with bodies to their own specifications as regards general design, equipment and finish.



Upper—Phaeton-landaulet by Bail Jeune Frères, Paris, on Locomobile 48 chassis, $7,500
Lower—Holbrook semi-touring car on Locomobile 48 chassis listed at $6,800

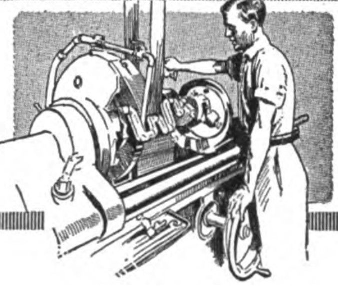
16-Year Contract for Motor Mail Man

SILVER CITY, N. M., Dec. 5—What is said to be the roughest and longest star route in the United States is that which runs from Silver City to Mogollon, 90 miles. The postoffice department has just let the contract for carrying the mail over this route by means of automobiles to C. A. Bennett of Silver City for $10,000 per annum. The contract runs for a period of 16 years. It requires that the first-class mail shall be carried six times a week and fourth-class mail three times a week. Besides using a light motor vehicle, Mr. Bennett will place a motor truck in service to transport the heavier packages, such as come by parcel post. The mountain road runs via Gila, Cliff, Buckhorn and Jackson, each of which towns are also served under the contract. The treacherous nature of the Gila river, which often goes on a big rampage, has caused an aerial tram to be constructed by which means the stream is crossed in a large cable car that runs high in the air. This aerial car is large enough to carry the motor truck, load and all.



Upper—Holbrook landaulet-limousine on Locomobile 38 chassis, selling for $6,150
Lower—Coupé by Henry Binder, Paris, on Locomobile 38 chassis, selling for $6,600

The Rostrum



This department is for the instruction of the readers and all are at liberty to ask questions. Be sure to give full name and address that we may send you a reply by letter if there is no space in the Rostrum. If you wish to sign a fictitious name, also sign your own.

Directions for Adjusting Main and Connecting-Rod Bearings

EDITOR, THE AUTOMOBILE:—I would like to have you explain clearly how to fit babbitt bearings on crankshaft and connecting-rods, either when putting in new ones or when taking up slack in old ones?

Cape Girardeau, Mo. P. J. LOUGHLIN.

—The treatment depends on the condition of the bearings. If only slightly worn, the bearings may be adjusted by removing shims or filing the bearing caps, depending on which method has been adopted. If the bearings are scored or worn out of round, or if new bearings are put in, the surfaces must be scraped.

If the bearing surfaces are in good condition and not worn out of shape, a slight amount of adjustment should be sufficient to make them tight. Generally there are several shims under the bearing cap and by removing these one by one, the looseness will disappear. A typical connecting-rod bearing with shims is shown in Fig. 2. Be careful not to remove too many shims so that the bearing cap will bind when drawn up. Remove only enough of the shims to make the bearing a snug, but not a tight fit. When shims are not used, the lost motion may be removed by filing the surface of the bearing cap as shown in Fig. 1. In case too much material is removed a copper or paper shim or shims should be inserted to make the cap fit. Care should be exercised in filing to preserve the flat surface of the bearing cap. This requires that the file not only be held flat against the surface but also that the movement of the file be carefully executed.

If the bearing is scored, worn out of round or if the bearing is new, it will need scraping. If possible this work should be done by an experienced man. Scraping of the connecting-rod bearings may be done without tearing the motor down but if the main bearings require scraping, the motor must be dis-assembled, the crankcase placed upside down on a suitable support with the crankshaft and flywheel still in place. We will describe the method of scraping the main bearings as this is more difficult than scraping the connecting-rod bearings. The main bearing caps are removed, and the crankshaft bearing surfaces are painted with a solution of Prussian blue. Then the crankshaft is rotated a few times and removed. The high spots of the bearings will be coated with the blue. These spots are carefully removed with a special scraping tool, care being taken not to cut too deep. Then the crankshaft is repainted, replaced in the bearings and rotated. In this way the high spots are once more determined. The crankshaft is removed and these spots cut off. By successive treatments, the few large high spots which there were at the outset have gradually given place to smaller and more evenly distributed ones until finally when the operation is completed these spots will be very small and uniformly distributed over the entire surface showing that the bearing makes contact with the crankshaft surface at practically every point. In a similar manner, the surface of the main bearing caps and the connecting-rod bearings should be put in condition.

Six Gives Smoother Torque

Editor, THE AUTOMOBILE:—1—Kindly tell me whether in general, six-cylinder motors are considered better than four-cylinder and why?

2—Give me a simple rule to compute horsepower.

3—Which is best, cone clutch or multiple disk?

Delmont, Pa. H. N. SMITH.

—1—The advantage of the six is that it has a smoother torque, that is, since it has two more cylinders there are three impulses instead of two, during each revolution. The result is that the six pulls better at very low speeds, and will accelerate more rapidly on hills. It runs smoother, especially at low speeds, because it is in better balance and the reciprocating parts are smaller per cylinder.

2—You may use the S. A. E. formula, in which horsepower $= \dfrac{D^2N}{2.5}$ where D = the bore in inches and N = the number of cylinders. This formula assumes that the piston speed is 1,000 feet per minute and that the mean effective pressure is 90 pounds per square inch.

Since a piston speed of 1,000 feet per minute is a low maximum for modern motors a more accurate result can be obtained from the modified S. A. E. formula in which the horsepower $= \dfrac{D^2NSR}{15{,}000}$, where D = bore in inches, S = stroke in inches, R = revolutions per minute, and N = number of cylinders. In this formula piston speed is taken account of by the stroke and speed in revolutions per minute.

3—Both seem to be equally good. Both may be found on the highest-priced and the cheapest cars.

Information on Welding and Brazing

Editor THE AUTOMOBILE:—I would be very pleased if you would furnish me with some information regarding welding and brazing processes or refer me to the proper

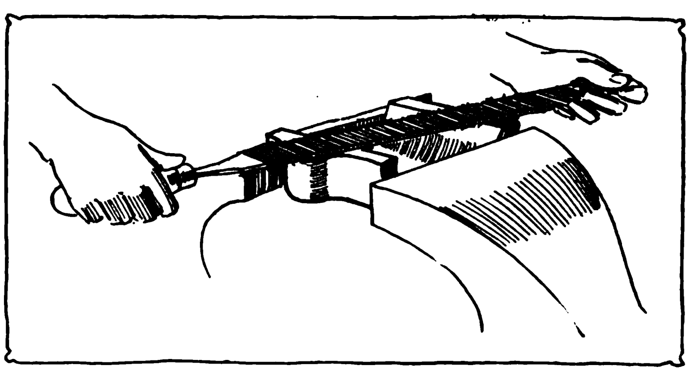


Fig. 1—Method of filing bearing. Care must be taken to put an even pressure on the file so that the same amount of material is removed on both sides

authorities for same. I do not see any advertisements or other information along these lines in your current issue.

Midville, Ga. J. R. NORTH.

Directions for oxy-acetylene welding were given in THE AUTOMOBILE for November 12 on page 885.

Brazing metals, which means that they are joined by a film of brass, requires a red heat and borax is generally used as a flux to protect the metal from oxidation and to dissolve the oxides formed. Heating must be done by means of a blow pipe torch, gas forge, coke or charcoal furnace and cannot be done by means of a soldering iron.

Before work is assembled for brazing it should be carefully cleaned. The parts are then fastened together, generally by pinning but sometimes wire bolts or clamps are used. If possible the pieces should be fastened in such a way that the work may be turned over during the process of brazing without changing the relation of the parts.

—The following are some books on welding and brazing: Hard Soldering, Welding and Brazing, \$1, J. N. Hobart, McGraw-Hill Book Co., 239 West Thirty-ninth street, New York City; Soldering and Brazing, J. N. Hobart, \$1, David L. Williams Co., 231 West Thirty-ninth street, New York City.

How to Solder Aluminum

Editor THE AUTOMOBILE:—Would you kindly give me any information you can on soldering aluminum?

Philadelphia, Pa. JOHN E. JAMES.

—Aluminum is soldered by the use of a blow torch. A solder which may be used without a flux is composed of 75.5 parts of tin, 18 parts of zinc and 2.5 parts of aluminum. The parts should be slightly heated before applying. The solder should be forced in place by means of a stiff metal brush. Another solder which requires a flux however, is made up of 80 per cent. tin and 20 per cent. zinc, stearic acid being used as a flux.

The objection to soldering aluminum is that the joint is not very strong. A solder which is claimed to overcome this difficulty is the German-American which was described in the September 17 issue of THE AUTOMOBILE on page 564.

This description is reprinted in part:

To dispense with the present oxy-acetylene method of repairing fractures in aluminum parts is the object of the German-American Aluminum Co. which has just established a sales office at 25 West Forty-second street, New York City.

The new solder is the invention of Karl R. Peters, a metallurgist of Berlin, Germany, and at the present time it is being manufactured in this city as well as in that country. The inventor claims that no breaks are too complicated to be repaired by the new method and that the work can be done at a saving of at least one-third the cost of the welding job. The strength of the solder, according to Mr. Peters, is about double that of aluminum as regards its resistance to tensile strains and even greater as regards its resistance to bending.

In performing the work on an aluminum casting that has been broken into a number of pieces, the various parts are matched as closely as possible and screwed down on a jig. The fractures are then chiselled in the form of a V-shape slot in the same manner as for a welding job. The solder, which melts at a temperature of 400 degrees Fahrenheit, is then run into the slot and finds its way down into crevises between the two pieces of metal. Upon solidifying the joint is made.

Mr. Peters states that he has had 8 years' successful experience with his solder both in this country and abroad. It is a secret composition, containing eight ingredients, five of which are metals and the other three salts of metals. The German-American company will either do the repair work itself at its factory at Port Jefferson, Long Island, or will sell the solder, together with territorial rights and instructions for its use in garages and repair shops. A guarantee is made that regardless of the work to be performed the aluminum will break before the soldered joint under any ordinary strain.

Motor Speeds at 10 m.p.h.

Editor, THE AUTOMOBILE:—1—How many revolutions per minute will the motors on the following cars turn running at 10 miles per hour: Studebaker, Model S.D.; Buick, C-24; C-25; Maxwell, 25; Overland, 81; Regal, D; Oakland, 37?

2—What is considered the most efficient ratio of stroke to bore?

New York City. M. CASSIDY.

—1—Knowing the gear ratios and the tire diameters of

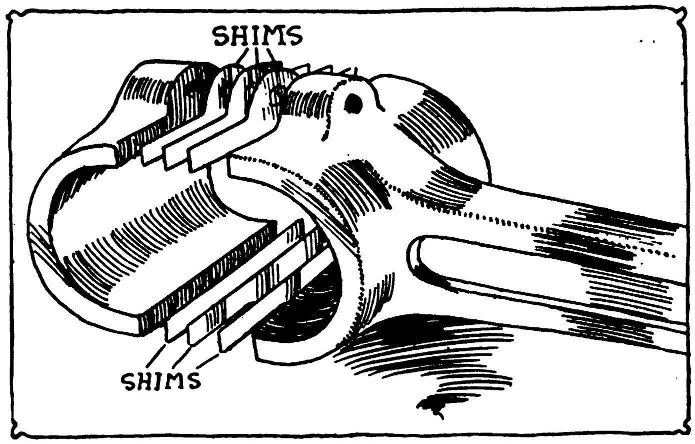

Fig. 2—Connecting-rod bearing end with cap removed to show shims

these cars, the motor revolutions at 10 miles per hour may be easily figured. Ten miles per hour corresponds to a certain number of feet per minute and this divided by the circumference of the tire equals the number of revolutions per minute that the rear wheel makes, in each case. Multiplying this quantity by the gear ratio, the revolutions per minute of the motor is found. Using symbols for the different quantities involved, the formula

$$M = \frac{S \times R}{D} \times 336$$

is found. M = motor revolutions per minute, W = revolutions of wheels per minute, C = circumference of wheel in feet, S = speed in miles per hour, R = gear ratio, and D = wheel diameter in inches. $\frac{S}{60}$ = speed in miles per minute and $\frac{S}{60} \times 5{,}280$ = feet per minute, then this quantity divided by the circumference of the wheel C gives the wheel revolutions per minute, $\dfrac{\frac{S}{60} \times 5{,}280}{C}$, then this multiplied by the gear ratio R will give the motor revolutions per minute, or revolutions per minute of the motor =

$$\frac{\frac{S}{60} \times 5{,}280}{C} \times R \text{ or } = \frac{S \times R \times 5{,}280}{C \times 60}$$

The circumference of the wheel C in inches is 3.14 multiplied by the diameter D in inches; divided by 12 this expression is reduced to feet. Therefore the circumference

$$C = \frac{D \times 3.14}{12}$$

Substituting this in the above formula

$$\text{r. p. m. of motor} = \frac{S \times R \times 5{,}280 \times 12}{D \times 3.14 \times 60}$$

$$= \frac{S \times R}{D} \times 336 = M$$

Using this formula, the motor speeds, since the tire sizes and gear ratios are given, are as follows:

	Gear Ratio	Tire diameter	Motor r. p. m. at 10 m. p. h.
Studebaker, S.D.	4 to 1	33	408
Buick, C 24, C 25	4 to 1	32	420
Maxwell, 25	3.58 to 1	30	400
Overland, 81	3.75 to 1	33	381
Regal, D	3.75 to 1	32	393
Oakland, 37	4 to 1	33	408

2—This is a matter of opinion but the average of the principal American motors for 1915 gives a ratio of 1.3.

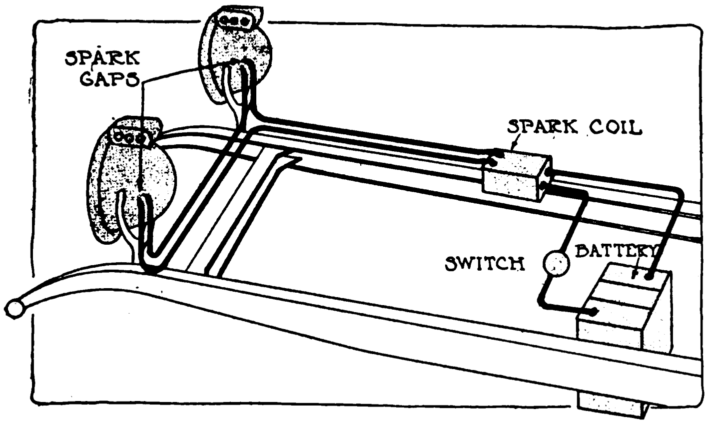

Fig. 3—Wiring to enable the lighting of the acetylene headlights by electricity

This may not be the most efficient ratio but it is probably close to it. It must be remembered, however, that the ratio must vary to a certain extent according to the size of the motor, being less for a large one and greater for a small one. The average bore and stroke of these motors is 3.82 by 5.1

Horsepower of Two and Four-Cycle

Editor, THE AUTOMOBILE:—1—What is the difference in horsepower between a two and a four-cycle motor having the same piston displacement?

2—Would the two-cycle have twice the power of the four?

3—What is meant by the word Baumé?

4—Who makes the Marsh one-cylinder air-cooled motor?

5—What is the right pronunciation of Mercedes?

Jamestown, N. Y. M. K. PALMQUIST.

—1 and 2—In motors of average design there is little difference in horsepower between the two. Although the two-cycle has twice as many strokes per revolution the mean effective pressure is generally not so high.

3—Baumé is a measure of the specific gravity of the gasoline with reference to a solution of salt and water, and the method was invented by a French chemist, Antoine Beaumé. The measuring is done with a Beaumé hydrometer which is merely an ordinary hydrometer with a special scale on it. Certain fixed points were first determined upon the stem of the instrument. The first of these was found by immersing the hydrometer in pure water and marking the stem at the surface of the water. This point formed the zero of the scale. Fifteen standard solutions were then prepared with 1, 2, 3, up to 15 per cent. by weight of dry salt and the hydrometer was immersed in these different solutions and corresponding marks made on its stem. Thus an arbitrary scale was formed for determining the densities of liquids heavier than water.

The hydrometer intended for densities less than water and which would be used for gasoline was marked in a similar way. A solution of 10 per cent. pure salt was used for the zero of the scale and the points at which the instrument floats in distilled water at 10 degrees Reamer or 54.5 degrees Fahrenheit is numbered 10. Equal divisions are then marked off up the scale as far as 50.

4—The concern that made the Marsh has been reorganized and is known as the Sterling Motor Co., Brockton, Mass.

5—This is a Spanish name for a girl. It is impossible to indicate the exact pronounciation but it can be approximated in English by giving the first e the same sound as the e in berry, the second e the sound of i in still but emphasized, and the last syllable should be pronounced as des in destroy. The accent is on the second syllable.

Questions on Ford Magneto

Editor, THE AUTOMOBILE:—Kindly explain the following questions concerning a Model T Ford magneto:

—1—What is the voltage, amperage and field resistance at 1,000 and 2,000 revolutions per minute and how can these speeds be determined?

2—What are the causes of a drop in voltage and amperage?

3—Explain how the magnets can be recharged by use of direct current through the magneto plug.

4—Does low resistance between the field terminals (caused by shunting in lights, electric horns, etc.) injure the magneto?

Newburyport, Mass. NORRIS C. INGALLS.

—1—There is no field resistance since the Ford magneto employs permanent magnets. The amperage depends entirely on the voltage generated and the resistance of the circuit. The voltage at 1,000 and 2,000 revolutions per minute is not obtainable but at 980 revolutions per minute the voltage varies from 16 to 24 depending on the condition of the magnets, it is stated.

2—In the Ford magneto drop in voltage causes missing at low speeds but in general is a drop in pressure, the same as when water flows in a pipe there is a certain drop in pressure between any two points. The drop in voltage, Fig. 4, is explained by studying the flow of water, which is opposed by a frictional resistance and if we have a pipe 2 inches in diameter and 100 feet long and have a pump which supplies water at 100 pounds pressure at one end, then the flow of water will be quite rapid so that a great many gallons will be discharged. The only force opposing the flow of the water will be the friction between the water and the walls of the pipe. If the interior of the pipe is rough more resistance will be offered than if it is smooth. If the pipe is made larger the resistance will be reduced and more water will flow. If it is smaller the resistance will be increased and less water will flow. Likewise if the pipe is lengthened to 200 feet the total resistance will be twice as great and only half as much water will pass through it.

The same may be said of the electrical wire. The volt is the unit of pressure and if 100 volts is applied to 100 feet of wire of a certain diameter a current flow of a certain number of amperes will result. It has a certain electrical resistance which opposes the flow of the current the resistance varying with the material of which the conductor is made instead of according to the roughness of the surface as is the case with the pipe. This resistance also varies with the area of the wire, the larger the wire the less the resistance. Also the resistance depends on the length of the wire.

If the resistance of the conductor is reduced by shortening it, by increasing its diameter or replacing it with a material which has a smaller resistance then the current flow in amperes will be greater and likewise if the resistance is increased in any way the flow will be reduced. If the voltage or electrical pressure is increased and the resistance remains constant then the flow of current must increase and if the pressure is lessened it must decrease.

In a wire of uniform size and material the drop in voltage is uniform from end to end because the resistance of any small unit of length is constant.

3—Six fully charged, 6-volt, 60-ampere storage batteries, a compass and some wire are required for charging the magnets. The storage batteries are connected in series and the negative wire is grounded on the car. The positive wire should have a rod attached to its end and then the magneto plug should be removed and the rod thrust in to make contact with the magneto inside the cover. Place the compass a small distance behind and to the left of the hole for the magneto plug, and have someone turn the motor over until the needle points to the front of the car. Then open and close the circuit by removing the negative wire from the car. The circuit should be held closed for 6 seconds at a time and then broken, twenty-five times.

4—The low resistance is not of itself injurious but if the resistance is low enough to allow a heavy current to flow, there may not be enough current for ignition or possibly the current will be so strong that it will heat the coils and hurt the insulation.

Questions on High-Speed Motors

Editor THE AUTOMOBILE:—I noticed in one of your recent issues a short article by Charles Duryea on How Rotary Valves Are Timed. I have not had the opportunity of reading the previous discussion therein referred to and would like to be enlightened more particularly on this subject.

1—In timing the intake valve is not the only essential that said timing be so arranged that the gas will have been started through the manifold by a sufficiently early opening as to be ready to supply the greatest volume of gas during the instant of greatest opening of valve and that such maximum opening be sustained during the period of greatest suction or piston speed?

Mr. Duryea contends that gas having started through the manifold while suction existed will continue to ram in after the compression stroke has started. In the Deltal motor described in your columns some time ago, the intake closed 48 degrees past dead center. In your opinion through how many of the 48 degrees of the compression stroke would gas continue to ram in?

2—Was any gas backed out?

3—Is it not a fact that during most of this 48 degree period, the poppet valve remains open only because it is not deemed advisable to shape the cam so as to allow the valve an immediate drop and close?

4—In that same Deltal motor the exhaust opened 68 degrees before dead center and closed 8 degrees after. Is this extremely long opening of exhaust the secret of the high speed attained by this motor?

5—Did not considerable power waste through the valve between the time of its opening and say 20 degrees before lower dead center? Did not the valve at such early opening lift against greater pressure than would exist at 20 degrees before dead center?

6—Is it not a fact that early opening of an exhaust valve of the poppet type is deemed advisable solely for the reason that such an opening affords means of reaching and sustaining the maximum opening throughout the scavenging stroke?

7—If an exhaust valve of the rotary type was supplied that opened 20 degrees before dead center and closed 8 degrees after, but which provided an extra quick and very large opening such that would permit a free and easier exhaust to even a greater volume of exhaust gas than the Deltal motor handled, and if such valve were easier of actuation than the Deltal type, would not such a valve make for more power and more speed?

8—In producing a special high-speed motor the reciprocating parts are made as light as possible. Am I right in assuming that these reductions are made in order to offset the power absorption of the larger valve gearing used, and thus register a greater power than can be obtained from stock motors?

9—Should not the opening of the exhaust valve be governed largely by the length of the stroke?

10—In a rotary valve motor of 4-inch bore and 6.5-inch stroke, equipped with extra large straight passage valve ports and with easily actuated valves and gearing, etc., in which the intake opens 8 degrees after dead center and closes 20 degrees after next dead center, and in which the exhaust opens 20 degrees before dead center and closes 8 degrees after next dead center, in your opinion would a change of such timing to that of the average of 60 engines mentioned by Mr. Duryea, be a change for the better? or worse?

Pittsburgh, Pa. B. D. GAMBLE.

—1 and 2—The object in delaying the closing of the intake valve is to allow the intake to ram in, as Mr. Duryea terms it, after the compression stroke has started. This effect only occurs at high speed. At ordinary rates of revolution a small amount of gas might be pushed back out of the intake valve. At high speed the gas, due to its inertia, will continue to flow in all the time the valve is open, that is through the 48 degrees of opening. However the piston movement represented by 48 degrees on a motor with 5-inch stroke is only .4 inch and therefore only a small amount of gas will be forced out.

3—Yes. Whether the cam allows a quick closing or not is a question of whether silence or maximum power is the more important.

4—Partly. The high speed is due mainly to two things: The amount of combustible mixture taken into the cylinders and the rapidity with which the exhaust gas is disposed of, thus reducing the back pressure. In order to obtain the former, at high speeds, the closing of the intake valve must be delayed. To accomplish the latter, the valve is opened before the piston reaches the end of the expansion stroke. A small amount of the expansive force is lost by so doing but this is more than offset by the gain which results from having a reduced pressure on the piston at the first part of the exhaust stroke.

5—A small amount of power is wasted at low speeds only with this early opening. Regardless of the speed the energy in the gas is largely spent before the exhaust opens at 68 degrees before lower dead center, its expansive force is nearly gone, and its pressure is very low compared with what it was at the beginning of the stroke. When the motor is running slowly some power is wasted but as already explained when it is operating at high speed this loss is more than made up for by the reduction of back pressure.

6—Yes.

7—This rotary-valve motor might develop more power than the ordinary touring car type at touring car speeds but it would not be apt to show the power at high speeds.

8—The reciprocating parts are made light to reduce vibration.

9—The time of opening of the valves, if this is what you mean, depends on the maximum speed of the motor and whether it is to be used for touring or racing, but the size of opening is governed by the piston displacement and maximum speed desired.

10—Mr. Duryea's timing is preferable. He states that the exhaust should open 45 degrees before bottom center and close 8 degrees after top dead center.

How to Wire Gas Lighter

Editor THE AUTOMOBILE:—Will you kindly advise me what is the proper way to wire an electric lighting system for gas head light? Shall I have one coil vibrator for each lamp or just one coil for both?

Houston, Texas. JOE TESORO.

—One coil for both lights should be sufficient. Make the gaps spark small, say not over 1-32 inch, putting the two in series. The wiring is shown in Fig. 3. You might wire the ignition coil to produce the required sparks but without knowing the type of coil you have, details can not be given.

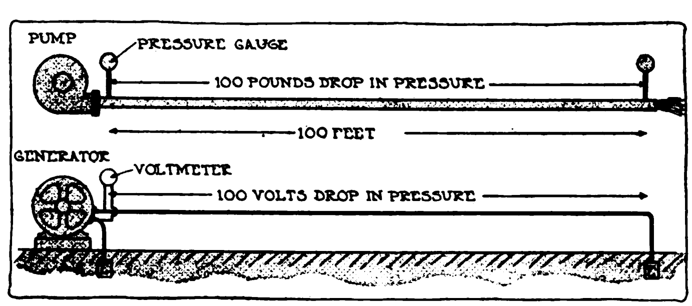

Fig. 4—Diagram showing the relation between the flow of water and electricity

The Engineering Digest

Recent Progress with Alloys—Theory Explaining Self-Hardening Metals Including the Special Steels

SIMPLIFIED HEAT TREATMENT GAINED BY SKILFUL STEEL MAKING

EVERY day, almost, sees new alloys of metals which are placed in the market with a view to the attainment of definite industrial purposes. They have usually been developed at research laboratories, and the improvements which they represent relate to their manufacture, their composition and properties or to their heat treatment. While not entering upon an account of the progress made in smelting, casting, forging and rolling, Leon Guillet, the well-known metallurgist, presents in eleven recent issues of *Génie Civil* a somewhat detailed report of the improvements made in the past few years in the properties of alloys as due to modifications in their composition or the manner of working them. As complicated heat treatment has not been found industrially practicable, by reason of the uncertainty of the labor element and the cost, the improvements in working methods go in the direction of simplification and the reduction of machine work. The self-hardening steels now much used for automobile gears and other parts in France furnish an example of the combination of great strength and durability with simple heat treatment and small correction for distortion.

A few passages from Professor Guillet's account are here rendered with omission of most of the technical explanations and reasonings, as these could scarcely be made intelligible in abbreviated form.

General Principles

Alloys show sudden variations, in their solid state, of some of their properties, such as their specific heat, their expansion or volume, their electric resistance, magnetism, etc., and these variations can be due to a transformation which the whole mass of metal undergoes as a unit, or to reactions among its components or to transformation of one of these. The changes brought about by heating and quenching are of the greatest industrial importance, being intended to increase strength and hardness or resilience. The effect of quenching is to preserve in part the condition which is stable in the metal at the temperature at which the quenching takes place, this effect being obtained by the suppression of the transformation which would take place during slow cooling.

The first condition for being able to harden an alloy by quenching is thus that it naturally undergoes a transformation at a certain temperature, and this fact indicates the importance of metallurgical diagrams for the metal industries. The second condition is that the temperature of transformation is at least reached before quenching takes place. As changes are not instantaneous, it follows also that the heating must last long enough to make them complete, if the full effect of quenching shall be obtained. Finally, as the speed of reactions generally grows with the temperatures, it is pertinent to inquire if it is not advisable to heat to a temperature above that of transformation.

Only in the case of certain nickel and manganese steels is it found that the condition existing before the cooling is completely maintained after it. In all other cases there is after the hardening process always a partial return toward the normal state of the metal. It can therefore be said that while industrial hardening imparts to an alloy a different structure from the normal one it is not the same which exists above the temperature of transformation. In the case of steels, for example, the malleability and high resilience existing above the point of transformation are much reduced in the cooling, and magnetism is restored, but the structure which is characterized by fine martensitic needles at the high temperature is maintained.

In this connection it is observed that if an alloy is heated too far above the point of transformation before quenching, the martensite becomes more and more visible under the microscope, coarser and thicker, and this structure, which detracts from the desired mechanical properties of the metal, is more stable for the high temperature than the finer martensitic structure and is therefore preserved more fully by quenching, as is also shown by experience to be the case. The quenching temperature should therefore never be more than 50 to 75 degrees centigrade higher than the highest transformation point of the alloy.

The Critical Points

That there can be question of a higher and a lower transformation point is due to the phenomenon of hysteresis, which causes the transformation to come at a higher temperature during heating than during cooling. Usually this difference is small, but for some compositions it is pronounced, and recently this phenomenon have been turned to important industrial account. Another factor, besides the composition of the alloy, influences the hysteresis, as for certain alloys it is stronger the higher the temperature is carried, at least within certain limits.

The principle of the influence of composition is shown most strikingly in nickel steels, where a nickel content of up to 25 per cent. lowers the critical or transformation point in the manner shown in the classical Osmond curve reproduced in Fig. 1, which may also serve to illustrate the industrial importance of hysteresis. Consider an alloy whose critical point during heating is at the temperature T while during cooling it is at t. To make such a metal take a temper it must be heated to above T to bring about the required molecular change, but to obtain the maximum effect from the quenching the latter should take place in the neighborhood of t. One should heat to T + 50 degrees and quench at t + 50 degrees. In practice, unless the hysteresis is pronounced, the differences in properties is not very great.

But suppose that t lies below ordinary temperature. In that case no retransformation will take place if the metal is left alone, and the alloy will be self-hardened and will have at ordinary temper-

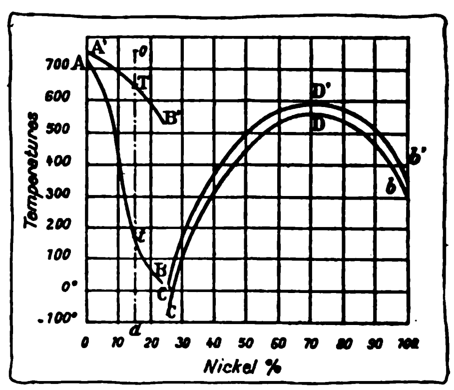

Fig. 1—Curves of critical points in nickel steels; for heating A' B' C' D'; for cooling A B C D

atures the structure which is stable for ordinary steels at high temperatures. This is the situation with steels high in nickel and manganese.

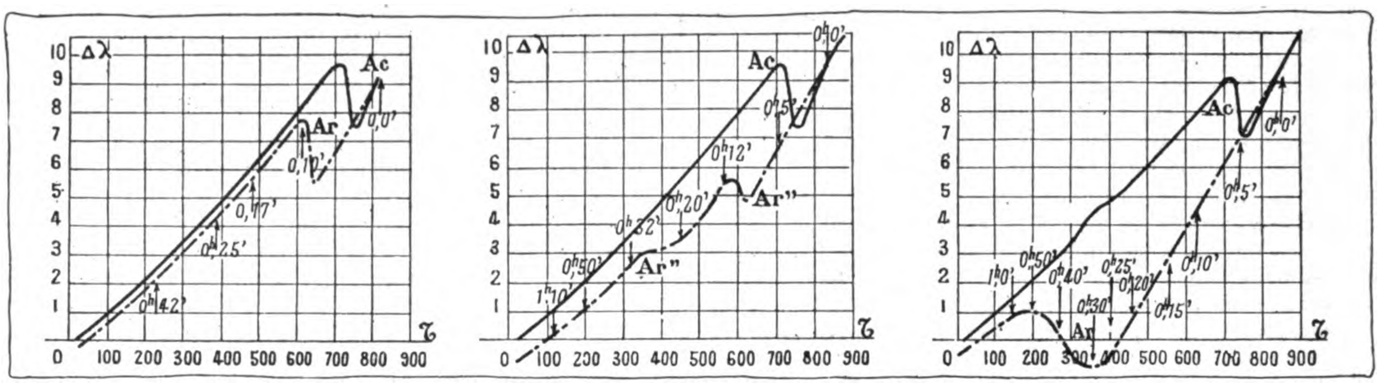
If, however, *t* lies somewhat higher, as at 200 or 300 degrees, and the metal has been heated to above T and is left to itself, it should change back to normal from the high-temperature structure upon reaching *t*, but at this relatively low temperature the molecules have small mobility and the components remain very much divided in their colloidal state; the structure is then that of ordinary hardened metal, combining properties of both the heated and the cold conditions and characterized structurally by fine martensitic needles; or by osmondite flakes which color easily.

In other words, alloys so composed that T comes high but *t* at a temperature at which the metal stiffens considerably can be hardened by heating them to above T and then leaving them alone. It is an obvious objection that such metals must have been heated above T in their manufacturing processes —the smelting, forging or rolling—and therefore must be pears and Ar" alone remains, and the metal becomes irreversible or almost so. [This seems to mean that reheating to just above Ac does not restore Ar readily to its previous place.] According to statements from the steel works at Imphy, where these diagrams were produced, certain chrome-nickel steels can be made semi-reversible or altogether irreversible according to peculiarities in the heating. The same phenomenon has been turned to practical account in the case of certain copper-zinc brasses.

Some aluminum alloys, when cooled suddenly at certain temperatures, show no immediate changes in their properties, but after some time has elapsed their hardness increases, and for this peculiarity no explanation has yet been vouchsafed.

Self-Hardening Chrome-Nickel Alloys

The industrial steels which are self-hardening by reason of a large hysteresis depending upon their composition contain nickel, but if this alloy metal is used alone to produce the self-hardening property, the strength and the hardness



Figs. 2, 3 and 4—Variations in the critical transformation points of certain chrome-nickel steels, as determined by the temperatures reached in heating the metal

too hard to be worked. But it has been found, empirically, that alloys of this nature can be softened by reheating them as closely to T as practicable without danger of reaching this temperature—in practice to T minus 25 degrees centigrade—by which operation they lose some of the mechanical effects of hardening while retaining the structural peculiarities and the ability to return to the hardened state when the temperature is again reduced.

Metals of this description, in which *t* lies at about 300 degrees and T usually 400 to 500 degrees higher, are thus of great industrial value in all cases where their physical properties in the hardened state are those desired, the heat treatment being much simplified. They should not be confounded with high-speed steels which follow different laws. In certain chrome-nickel steels the self-hardening principle finds important applications subsequently referred to.

Irreversible by Overheating

The influence upon the hysteresis of the temperature to which the heating is carried has been known for some years, especially so far as chrome-nickel steels are concerned, and is illustrated in Figs. 2, 3 and 4. [These diagrams are based on measurements of the expansion of the steel; Mr. Guillet shows also others based on heat measurements and thermomagnetic recordings]. It is noticed that the heat reached is about 800 degrees in Fig. 2, 870 in Fig. 3 and 900 in Fig. 4. The rate of cooling is indicated in minutes elapsed. By noting the locations of the points of transformation it is observed that this point, Ac, for the heating curve remains approximately constant but that, for a constant rate of cooling, the critical point Ar of the cooling curve drops considerably lower where the temperature has been higher. Moreover, this point, Ar, repeats itself in two places still lower, Ar' and Ar", if the heating has been such as to produce this result, as in Fig. 3. By increasing the heat still further, Ar' disappears

after tempering [which, it is noticed, is a process similar to annealing of ordinary steels] are not sufficient for such industrial purposes as would economically justify the use of a special and high-priced steel. When chromium is also added, however, the result becomes quite different, and it is for this reason that self-hardening chrome-nickel steels lately have entered widely among those used for automobile construction.

The physical properties shown by the best known brands of these steels are of interest.

One of them claims separate attention, being among those developed most recently and combining the qualities of the best steels in the two classes mentioned afterwards. It contains: C = 0.28, Mn = 0.32, Si = 0.19, Ni = 5.67 and Cr. = 1.05. Its critical point lies at 725 degrees on the heating curve and at 390 degrees for cooling. Annealed at 650 degrees this steel gives an ultimate tensile strength R = 94.1 kilograms per square millimeter, an elongation A = 14.7 per cent., a reduction of area S = 53.5 per cent. Shocks lengthwise of fiber with the ramming machine registers 10.9, crosswise shock 6.9, the hardness 264 Brinell.

Heated to 850 degrees and self-hardened it gives the following properties: R = 186.3, A = 7.5, S = 29.3, lengthwise shock 5.6, crosswise shock 2.7, hardness 482.

The shock tests were made on test pieces of 10-millimeter square section with notches 2 x 2 millimeters, and the figures refer to the resilience, giving the number of kilogram-meters absorbed in the test piece per square centimeter of working section. The Brinell figures refer to 300 kilogram pressures.

The other self-hardening steels in actual use come in two classes. In the first one the carbon ranges from 0.20 to 0.30 per cent., the nickel from 3 to 5 per cent. and the chromium from 1 to 2 per cent. In the second class the carbon ranges from 0.10 to 0.20 per cent., the nickel from 6 to 7 per cent. and the chromium from traces to 2 per cent. [Guillet here gives tables with the test figures in full for 5 steels in the first class and 3 in the second, but the general remarks on the showing made in these tables may here be sufficient.] In both classes the high critical point averages about 820 degrees and the low one about 410. The first class shows the higher tensile strengths, elastic limits and hardness, and the second class the higher resilience, especially for lengthwise shocks. High manganese and little chromium in one of the steels in the second class, with the nickel 6.45, produces brittleness however, as it takes this brand into the manganese steel class.

Practical Uses

In accordance with this showing the steels of the first class are indicated for gears and those of the second for rods, steering knuckles and parts similarly subject to brutal shocks. In practice it has been found that none of these steels fail by reason of brittleness, as their high elastic limits —reaching up toward 185 kilograms per square millimeter— are supplemented by a resilience of 4 to 5 kilogram-meters in their hardened condition. It might rather be said that they suffer from a certain lack of superficial hardness when used for gears. They have not always borne out the test figures, but this has been ascribed to faulty gear cutting or mounting of the gears, while it has also been maintained that gears properly machined from the start polish and harden themselves on the wearing surfaces by use, acquiring properties superior to those possessed by them when new.

However this may be, these steels have one important shortcoming in their high price, and this is due not so much to the nickel and chromium contents as to the great care which must be taken in their manufacture, or, more correctly, in their selection. Every melt, every ingot must be studiously investigated and must go to the discard whenever it shows even minor variations in its composition from the standard required in each case.

With regard to the relative effects of chromium and nickel in producing the self-hardening properties, the greater or lesser responsiveness of the alloy under the variations of temperature and the shadings of the final properties of interest to the steel worker or the buyer of the industrial products, Mr. Guillet sets forth a series of conclusions, apparently of great interest to steel makers, and also the chemical industries. It is brought out, for example, that the second class, above mentioned, of self-hardening nickel-chrome steels blends into a third class, in which a portion of the chromium fails to go into metallic solution and forms into carbide, with the peculiar result that the steel becomes highly refractory to ammonia and nitric acid.

—

Example of Four-Wheel Drive Truck Used for War Purposes—Rules Governing the Requirements

At the military trials of subsidized French motor trucks, which had almost come to a close when the European war began, the vehicles in which all four wheels are driven played a conspicuous part, as it had become realized that they would be found almost indispensable for heavy transportation work that could not take place on hard macadamized roads. Three hundred four-wheel drive trucks are now said to have been taken into use in the actual warfare and to have justified the expectations entertained with regard to them, so far as their ability to overcome all sorts of traction difficulties is concerned, while little has become known with regard to the amount of maintenance work required for keeping their special transmission mechanisms in working order under the unusually severe conditions, the very hardest work, across soft fields and ditches and over the steepest grades, being their constant lot.

Some details of the design of the Blum-Latil trucks, which came through the preceding trials with flying colors, are under these circumstances of interest. They are taken, together with the illustrations, from an ante-bellum issue of *Omnia*.

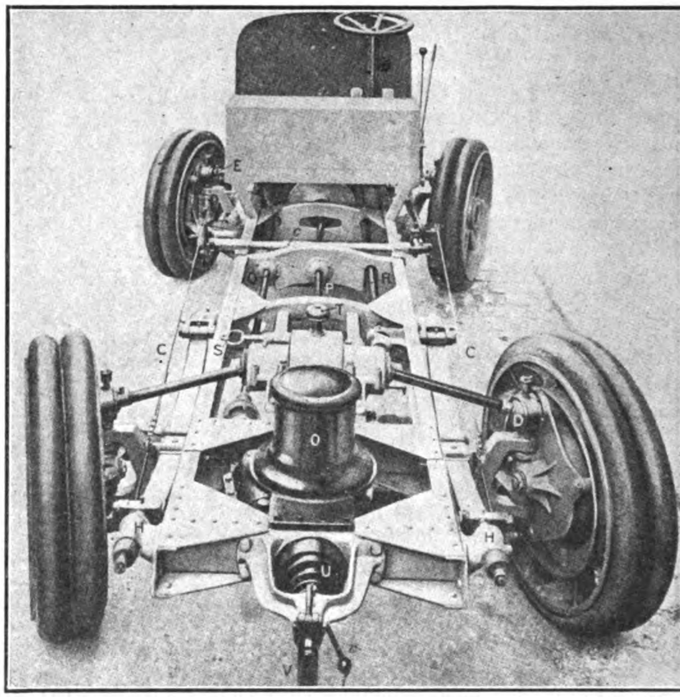


Fig. 5—View from rear of Blum-Latil tractor-truck

An advantage in the all-wheel drive system which has rarely been mentioned is here at once noted—see Fig. 6. As the front wheels are driven they can be loaded more heavily than in ordinary trucks without endangering the steering, and the motor can therefore be placed entirely ahead of the front axle, leaving more loading space for a given length of wheelbase.

The actuating of the front driving axle is much simplified by the same disposition, as it becomes possible to accomplish it, as is here done, by means of a short transverse shaft directly from the gearbox, the latter being mounted, by the way, as a unit with the motor. The rear axle is driven by a shaft from the gearbox in the customary manner.

Each axle has its differential, but that of the front axle is located inside of the gearbox. All of the wheels have speed-reducing gears driven through transverse wheelshaft with universals, and as the vehicle is broad-gauge the wear of the universals is considerably reduced, as compared with a similar driving system for pleasure cars. Both differentials can be locked, to help in overcoming traction difficulties on slippery ground.

All four wheels are steered, and it may be noted in the illustrations that the shaft which transmits the steering effort to the rear wheel pivots are of very large dimensions to secure the rigidity and freedom from torsion which are necessary to make the four wheels turn in perfect unison. There are also brakes on all four wheels and they are actuated simultaneously from the same hand lever by means of two cables, one to each pair of wheels and each with a compensating lever. Like the wheelshafts, the brakeshafts connect with universals mounted in vertical alignment with the axes of the steering pivots.

A special feature in the spring suspension is the lengthwise journaling of the spring shackle housings—or the pins, as the case may be—in the spring brackets, with additional resistance springs in the latter; this provision obviating the torsion of springs when only one of a pair of wheels is raised over an obstacle. Other construction details, such as those relating to the winch and the hooks for the attachment of a trailer, will be noticed in the illustrations.

The rules under which four-wheel-drive trucks are built for military uses in France express of course the opinions

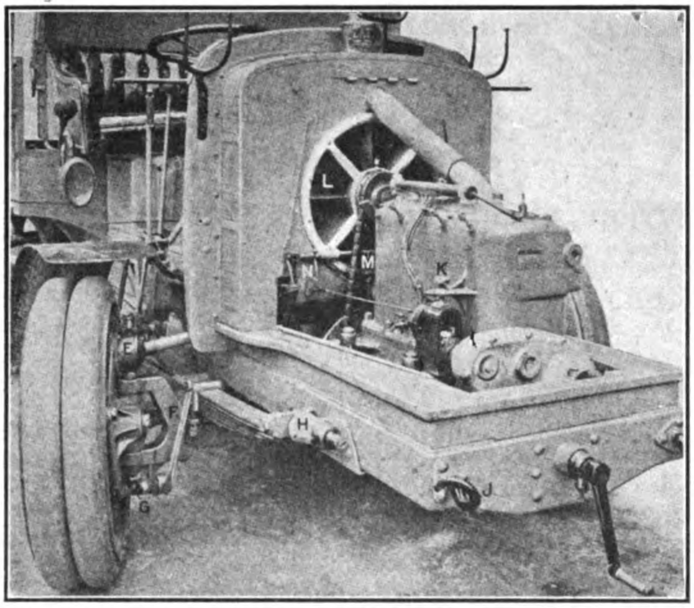

Fig. 6—Over-reaching front end of Blum-Latil truck. F, brake levers; H, pivotal spring brackets; K, set-screw for mounting magneto

which prevailed before the present war enlarged all previously gained experience on such subjects, and these opinions may have been modified on more than one point, but they still have a general value, and the more important ones among them are given in the following.

For emergency transportation work, of a civilian character, such as that which is required in connection with excavating and mining, they might be found even more useful than for the military work for which they were drafted, provided it is considered that the four-wheel-drive system, as applied to business purposes, can justify its constructive complications in other vehicles than those of the electric or gas-electric types.

Regulations for Four-Wheel-Drive Trucks

Weight Limit.—Must carry a payload of at least 1,500 kilograms, and the payload must be at least one-half of the weight of the empty vehicle. No axle must be loaded with more than 60 per cent. of the total, whether vehicle is loaded or empty, and under no circumstances with more than 4,750 kilograms. Maximum weight of vehicle and load 8,000 kilograms.

Traction Efficiency.—Empty the vehicle must be able to haul a trailer weighing twice as much, with its load.

Body.—Driver's seat must be sheltered and there must be seats for two beside it. Body at least 3 meters long, 1 1-2 meter broad with sideboards at least 60 centimeters high.

Turning Radius.—Diameter of smallest turning circle, measured to outside tracks, not to exceed 15 meters.

Wheels.—Front and rear wheels alike, with twin solid and continuous rubber tires (or equivalent substance) on smooth turned metallic rims either 850.6 millimeters or 1 meter in diameter.

Brakes.—Two sets required, one acting on transmission, the other on wheels; one operated by hand, the other by pedal.

Gear Speeds.—At least four and reverse. Low speed must develop at least two-fifths of the total loaded weight in pull at the hauling hooks, on good and level roads.

Devices Required.—It must be possible to lock the differentials. There must be two hooks at the front as well as at the rear of the frame, so that vehicle can both haul and be hauled. They must endure a pull of 2,000 kilograms and be suited to have cordage 40 millimeters thick looped into them. At the rear there must also be a spring hook, artillery model. A sand box to be operated by the driver from seat. A winch or similar device actuated from motor by irreversible gear and admitting of ready removal of cable, whether latter is under pull or not. Arrangements for pulling forward as well as rearward.

Cooling Capacity.—Sufficient to permit stationary operation for 30 minutes with power needed for hauling loaded trailers.

Hill-Climbing.—With maximum own load 18 per cent. grades; with trailer load in addition 12 per cent. grades on hard roads. By winch the trailer load on 15 per cent. grades.

Brake Capacity.—Sufficient to stop with trailer on 10 per cent. grade without recourse to brakes of trailer. Sufficient to anchor vehicle on 15 per cent. grade and haul trailer load by winch.

Rules for All Trucks

A number of the regulations are the same as for ordinary motor trucks with the ordinary driving system, while there are also many rules for the ordinary trucks which do not apply to the special class. All rules are of course at present somewhat relaxed. The rules in common are:

Anti-Skidding.—Means for easy attachment of traction chains or equivalent devices; they must not project beyond the rim of wheel and must keep coils of chain separate and evenly spaced.

Total Width.—Of vehicle, must not exceed 2.20 meters.

Road Clearance.—All organs must be at least 30 centimeters above the ground when vehicle is loaded. The wheels and organs thereon form exceptions.

Screwthreads.—Bolts, nuts and threaded pins must follow international system, if the parts serve for the assembling of two pieces, but not if they serve for adjustments.

Radiator Protection.—Radiators must be effectively armored by strong screens against accidental collisions.

Sprags or equivalent devices are compulsory. The construction and manner of mounting *magnetos* are hedged with many detailed provisions looking to interchangeability.

A *mirror* for looking backward must be provided, or an equivalent device. Also suitable tool *boxes* or *drawers* and one or more boxes to receive the baggage of three men, totaling an interior volume of at least 100 cubic centimeters. No box must have any dimension less than 0.20 meter.

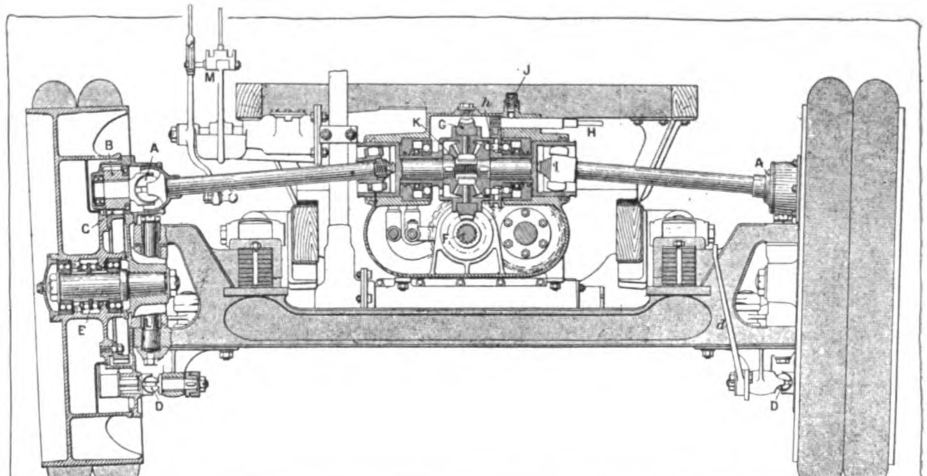

Fig. 7—Section of transmission; similar in front and rear. A, universal; BC, reduction gear; D, universal for brake; F, longitudinal drive shaft; G, worm gear for winch drive; H, lever for locking differentials with lugs *h*; K, differential; M, gear lever and quadrant

Care of Truck Springs

Overloading and Overspeeding Injurious to Suspension—Loading Problems—Resetting Worn-Out Springs Not Economical—Clips Must Be Kept Tight and Inspected Each Week

By John G. Utz,
Perfection Spring Co.

SPRINGS are probably called upon to stand more grief and punishment than any other part of a heavy-duty truck. The variation from no load to full load is so much greater than on a pleasure vehicle that it is worthy of attention.

Assume a 3-ton truck to weigh 8,000 pounds, or 4 tons, above the springs. When loaded a strain of 7 tons is upon the springs against 4 tons empty, a gain of 75 per cent.

A pleasure vehicle weighing 2 tons is only asked to take an additional passenger weight of 1,200 pounds, or a gain of 30 per cent. These figures indicate that the truck springs must handle close to two and one-half times the variation of a seven-passenger pleasure vehicle.

Use Rating Plate

This comparison of weight increase, due to carried load, refers to normal rated load only. In cases where overloading is practised it is evident that the gain is greater and, consequently, the springs are called upon to handle even greater variations. In most cases truck makers are attaching the rating plate in a prominent place, cautioning against loading beyond rated capacity, but we all know how these rating plates are disregarded.

Again, some truck makers allow for an overload capacity in their design beyond the advertised rated capacity, and when the spring maker is advised of such conditions, he is able to accommodate the same in the spring design.

Misleading Capacity

There is danger in letting it become generally known that a given truck is capable of handling a certain over-load, as many truck salesmen, in order to clinch a sale, will tell the prospective customer that, while the normal rating is, say 3 tons, "the truck is really designed to carry 5 tons." This is unfair to all concerned, as the customer immediately considers the vehicle as having a 5-ton capacity, and will load up accordingly, occasionally even exceeding this limit. The result is self-evident; all margin of safety disappears and the

EDITOR'S NOTE—*A paper read by John G. Utz of the Perfection Spring Co., Cleveland, O., before the convention held in Detroit, Mich., under the auspices of the Motor Truck Club of America, October 7-10.*

ultimate life of all parts is shortened accordingly.

The next item is the solid tire of the truck that throws additional vibration upon the springs. The frame of a truck is far more rigid than that of a passenger vehicle, which throws the distortion, due to road variations, upon the springs of the trucks.

Distribution of Load

Next, and of great importance, is the determination of load. In a pleasure vehicle the position of the carried load is predetermined, but on a truck the placing of the load is entirely up to the discretion of the driver.

The relation between bulk and weight of goods transported is widely variable, sometimes even in the same load. The necessity of evenly distributing such a load in proportion to weight instead of volume is a point that must be observed.

Quite often there is a temptation to place a heavy casting or piece of machinery on the very rear of the platform. A little thought and analysis will show that such loading throws a complex set of strains upon the springs that cannot but be harmful. Such a load should be placed in the middle of the platform right and left and as well as possible fore and aft.

The front end of a conventional truck has more or less constant load. At all events 80 per cent. of the load falls on the rear springs. It follows that the variable loading at the front end cannot be greater than the ratio of the load, reduced to pounds, to the weight of the motor equipment, cab, driver and helper.

Driver's Judgment Needed

Referring to the rear springs, since they carry 80 per cent. of the total load and, remembering that the load varies from nothing to as much as 50 per cent. overload, nothing but the intelligence of the driver stands between good and bad spring service.

Where Load Shifts

Another point of considerable importance in heavy duty trucks is the possibility of loads shifting, due to crowned roads. Many commodities, such as brick, small heavy castings, stone, etc., are given to shifting to the right side of the loading platform when driving on the right side of a crowned pavement. It is apparent that when a truck hauls nothing, for instance, but brick, and is continually driven on the right side of the road, the shifting of the load to the right side of the platform throws a more severe strain on the right spring than on the left, and it is quite apparent that the right spring will consequently fatigue long before the left spring. This may seem like a fine drawn theory, but there is definite knowledge of quite a number of cases where this very thing has occurred. Attention has also been called to certain vehicles, which, under full load, were standing lower on the right side than on the left. In these cases it was found that the load had shifted to the right and the truck was also standing on the right side of a crowned road, and difference as much as 2 inches or 3 inches between the two springs have been noted in such cases.

The Injury of Speeding

Speeding is probably the greatest crime that can be perpetrated upon an innocent truck. If a truck is moved along the road at 10 miles per hour under full load, it is more than likely that it will continue to do so for a very long time without exhibiting undue weakness at any point. But, if a truck is driven without any load at 20 miles per hour, remembering that the truck weighs more or less than 60 per cent. of the gross rated load, it is a certainty that the truck will wear out long before it pays for itself in service. It is not believed that the average driver fully understands how detrimental it is to the life of a truck to drive it at high speed when it is empty. The energy stored in a moving mass responds to the rule, which may for convenience be expressed as follows:

The energy stored in a moving mass is proportional to the weight in pounds multiplied by the square of the speed. In other words, if the speed is doubled, the strain is multiplied by four, and the life of all parts materially diminished.

Buy by Weight

In the economical production of commercial vehicles, in view of the present day competition, truck makers are reducing costs wherever possible, and since springs are sold by the pound, they are quite anxious to reduce the weight of the springs.

Springs Dissipate Energy

There is a point here worthy of attention. In the first place, the springs are called upon to absorb and dissipate energy, and there are only two ways in which this energy can be absorbed and dissipated, and both ways are in the form of friction. The two kinds of friction involved are internal and external, the internal being work done upon the molecular structure of the steel and the external in friction between the plates. The external friction is small, and with the present unwarranted demand for lubrication between spring plates, little reliance can be placed upon this form of absorption. This leaves the internal friction of the molecules as the only means of absorbing the desired energy. The more energy the molecular structure of steel is called upon to absorb, the sooner its power of absorption will be overcome. Therefore, it is quite evident that the larger volume of steel employed to absorb this energy, the greater will be the life of the springs. It is surely true that a certain amount of energy must be absorbed in the springs, and the more steel the more life. Hence, a reduction of steel means a reduction of life.

The Safety Factor

It also follows, where the springs are designed with sufficient steel to absorb the energy brought about by the normal rated load with a liberal factor of safety for overload; that, when the normal load is exceeded up to the overload, the factor of safety disappears; and when the carried load exceeds the overload capacity, the life of the springs will be reduced at an alarming rate.

Springs Wear Out

It should be borne in mind at this time that springs and tires are the two things on any motor vehicle which must wear out, since they are the only two items on a vehicle that are deliberately distorted in normal service. Fortunately for the truck maker (and unfortunately for the spring maker) springs do not wear out in as short a time as tires, but they ultimately must wear out. And when springs that have stood up to the mark for a considerable time begin to weaken and settle, it is time to replace the entire spring instead of having them reset.

Opposes Resetting

Resetting of springs is something like retreading a pneumatic tire, or putting a pair of half soles on an old pair of shoes. It is not economy to put a pair of half soles on an old pair of shoes where the uppers are practically worn out. We all know that retreading an old pneumatic tire is of little value as the carcass is near the end of its life; and for the same reason it is not good policy to reset an old pair of springs, as the molecular tension of the steel indicates that it is near exhaustion when the springs begin to settle, assuming the steel to be of corbitic micro-structure after heat treatment.

Keep Clips Tight

Spring clips should be inspected at least once a week and tightened as much as possible. If the clips become loose, the spring will break between the clips. If there is undue stretching of the clips, the difficulty might be overcome by having new clips made of better material, as it is always cheaper to replace clips which are too light than to have broken springs as a result.

The bearing place upon which the spring rests on the axle should absolutely conform to the curvature of the spring at that point, as sufficient bearing surface is just as important as tight spring clips.

Hints on Repairs

If a spring plate should break, it is important to have it repaired or replaced immediately by a skilled spring maker. Quite often a break in a plate occurs at a place where it does not immediately cripple the entire spring, but it is simple to understand that the breaking of one plate throws extra work upon the other plates which will break in turn. If one of the intermediate plates should break at the center bolt, the spring clips should be tightened down until it is possible to have the break repaired. Very often rebound clips are loose and broken. Missing rebound clips very often result in broken main plates.

On chain drive trucks there is always an ample allowance for adjustment to offset the stretch and wear of the chains. As the chains become stretched to a great extent, it is wise to remove an entire link and then shorten the adjustment so as to keep the spring shackles (at each end of the spring) standing at about the same angle.

A spring is a complete unit as produced by the spring maker. The removal or addition of a plate entirely disarranges the grading of the original plates, and should never be practised under any circumstances. It is also very bad policy to replace a broken plate by any plate that happens to be of the same width as the spring. It is far more desirable to let a competent spring maker attend to the repair or replacement.

In view of the preceding, there follows a list of things to be observed in the operation and care of the truck, if there is a desire to give the springs a fair chance to offer their longest life.

Rules of Reason

A—Evenly distribute load. Prevent shifting of load.

B—Do not overload beyond rated capacity. The factor of safety allowed by the maker is for the owner's protection as well as the maker's.

C—A wheel out of round due to flat spots on a solid tire, imposes a severe and dangerous shock upon the springs. Keep the wheels round.

D—Keep excessive side play out of shackles and hangers to minimize the lateral shock on the springs when on rough roads.

E—Give careful attention to all parts subject to friction. Keep them amply lubricated, as an excess of grease keeps the dirt out.

F—Take corners slowly, without or with load.

G—Back into a curbstone or platform gently as your radius rods might buckle and throw the jolt upon the springs. In driving the front wheels against a curb or any obstructions, the shock must be taken by the springs alone.

H—When loaded, drive gently over rough road or obstruction, remembering your frame is rigid and the springs must take the distortion.

I—Drive at moderate speeds at all times. Remember your solid tires have little resiliency.

J—If you have to tow a car, or have your car towed, hitch the tow-rope to the frame, not to the axle.

K—If an accident occurs, and a spring hanger, or the frame near the hanger is bent, have it straightened at once. A spring distorted by a bent hanger is liable to break under load.

L—When adjusting chains, remove a link when the adjustment would throw the shackles to a bad angle.

M—Keep spring clips tight at all times. If a center bolt should break, due to loose clips, replace it at once.

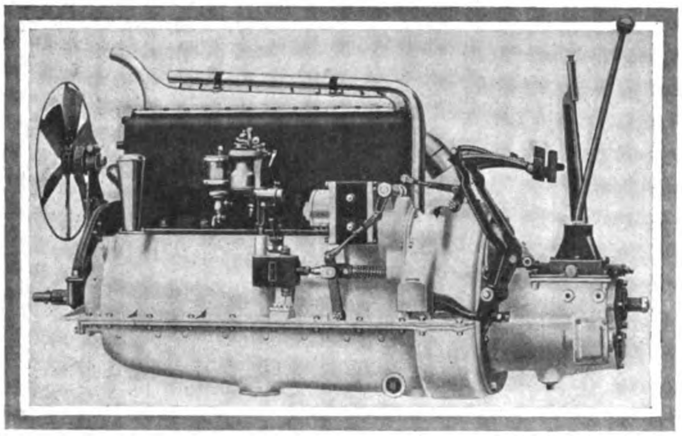
N—On a crowned road, drive as nearly in the center as possible, as driving to the right throws an extra load on the right-hand spring.

O—If a plate breaks, have it repaired by a competent spring maker at once, or the other plates will break in turn.

P—Tighten or replace loose or broken rebound clips.

Kissel Adds L-Head Block Six

New Model Has 3 5-8 by 5 1-2-Inch Motor—Electric Starting and Lighting and Vacuum Fuel Feed—Many Body Types

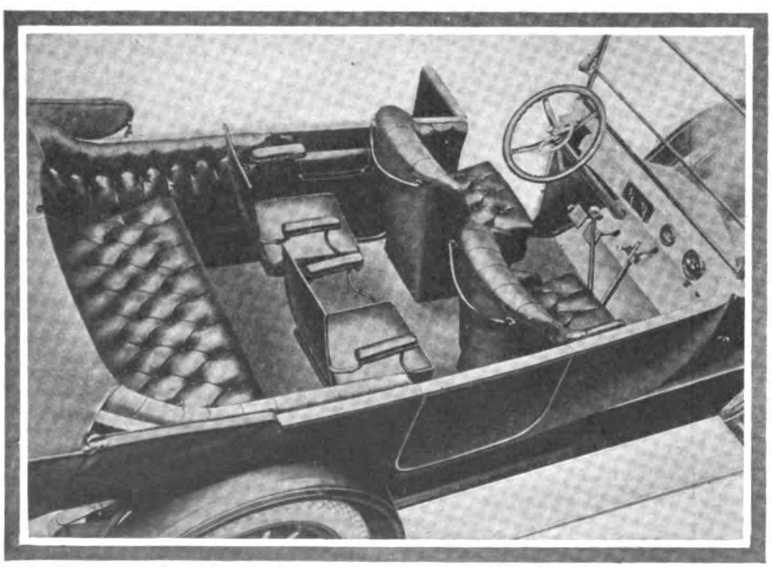


Left side of power plant used in new Kissel 42-six. The motor has a bore of 3 5-8 inches and a stroke of 5 1-2. Valves are 2 3-16 inches in diameter with heads of nickel steel

As the result of over a year's work in preparation and testing, the Kissel Motor Car Co., Hartford, Wis., has brought out a six-cylinder model embodying L-head block motor, three-speed gearset, 126-inch wheelbase, electric starting and lighting and complete equipment. This addition to the company's line lists at $1,650 fitted with five-passenger touring body with either two or four doors, or as a roadster. With seven-passenger body having three or four doors and oversize tires the car sells for $1,850, while with five-passenger touring body including detachable sedan top it is $2,000 and in coupelet form, $1,950.

The Motor

An L-head motor is used in the new model, which is called the 42-six, and the cylinders are cast in a block. The bore is 3 5-8 inches and the stroke is 5 1-2, giving an S. A. E. rating of 31.57 horsepower. The makers' rating, based on block performance, is 42 horsepower. Valves are 2 3-16 inches in diameter and are inclosed, together with the lifters. Valve heads are of nickel steel. The crankcase is an aluminum casting and, to insure maximum strength, the division is 2 inches below the crankshaft, which measures 38 1-4 inches over-all. The crankshaft is of special alloy steel and is carried on bearings 2 1-8 inches in diameter. The camshaft is of heat-treated alloy steel and is driven by wide-faced helical gears and is supported on white brass bearings.



New Kissel model 42-six fitted with special seven-passenger tonneau

The gray-iron engine cylinders are sand blasted and milled on a special machine, all holes being bored at the same time to insure accuracy and interchangeability. The heat treatment of the various metals used is all done in the Kissel plant, which is equipped with oil furnaces, dip tanks and electric pyrometers for this work. All chassis are tested by fan dynamometer.

Vacuum Fuel Feed

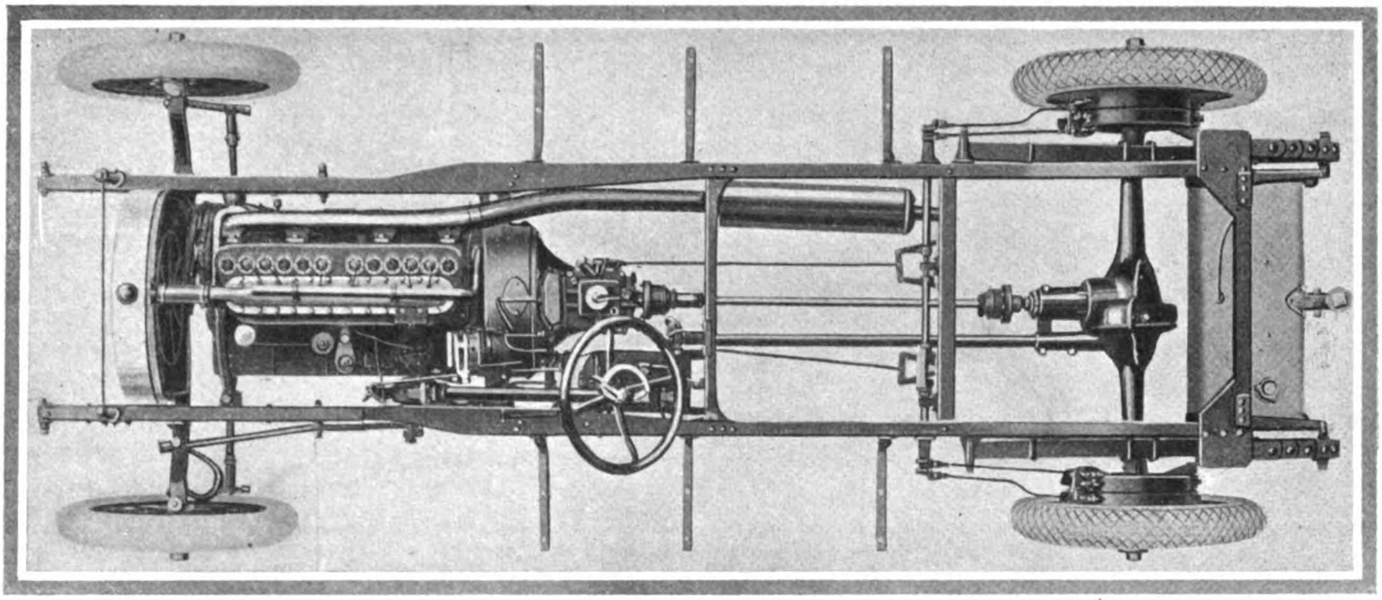
The lubrication system is by splash with a constant oil level maintained in troughs under the connecting-rods by a pump, whence it drains through a screen before being redistributed. The cooling water is circulated by pump through a Mayo honeycomb radiator through which a draft is induced by a 16-inch safety blade fan. The carbureter, which is a Stromberg of special design, is mounted horizontally and attached directly to the cylinders near the top, thus promoting accessibility. Fuel is fed from a 19-gallon main tank mounted at the rear of the chassis through a Stewart-Warner vacuum feed apparatus. The electric starter bears the Kissel nameplate and operates through gearing cut in the periphery of the flywheel, a foot plunger serving to engage the gears and connect the starter with the Willard battery, which is located amidships, under the floor. All wiring is centralized in a panel in front of the dash, thus facilitating the location of trouble and permitting the removal of the body without severing any wires in the electric system. The lighting generator is driven by gear from the engine. Headlights are provided with a dimming attachment.

Vanadium Steel Axles

From the motor, power is transmitted by a leather faced cone clutch, with adjustable spring inserts, to a three-speed selective gearset, the motor, clutch and gearset forming a unit supported on one bearing at either side and one bearing in front. Annular ball bearings are used throughout the gearset. The axle is of the floating type with vanadium steel driveshafts mounted, with the chrome-vanadium steel differential on Timken roller bearings. The differential gears are steel forgings, case hardened. The front axle is an I-beam section with vanadium steel steering knuckles and arms properly heat-treated.

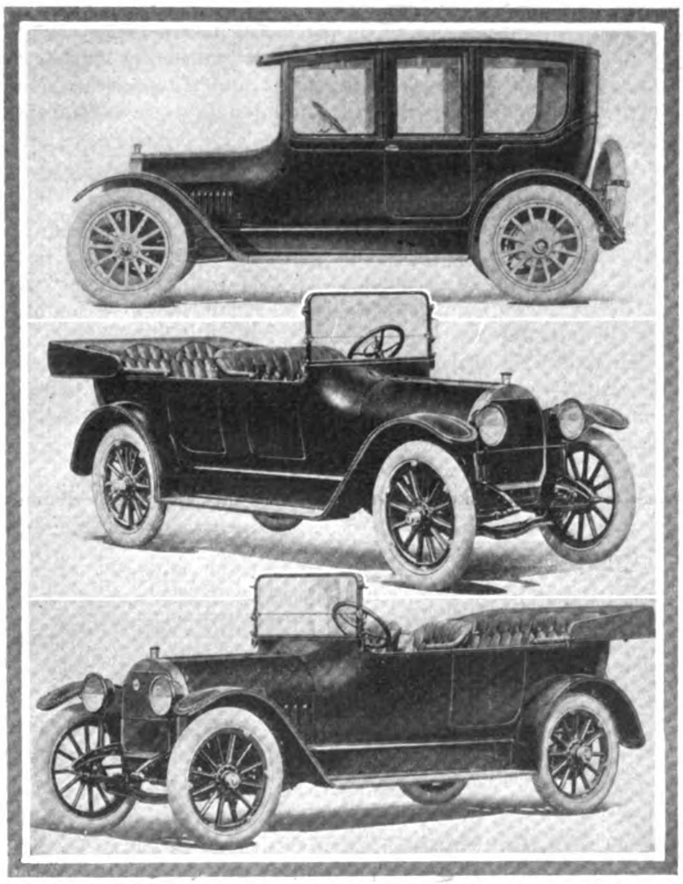
Easy Brake Adjustment

The pressed steel frame is arched at the front to give maximum clearance and permit of a short turning radius. It is mounted in front on semi-elliptic springs, 2 inches wide, and in the rear on three-quarter el-



Plan view of Kissel 42-six chassis, showing block motor, mounting of electric starting and lighting units and main fuel tank at rear. The speedometer is driven from the rear of the gearbox

liptics 2 1-4 inches wide. Both sets of brakes are external contracting on 14 by 2-inch drums mounted on the rear wheels. There is a hand nut arrangement for easy adjustment. With the exception of the seven-passenger model, which is mounted on 35 by 4 1-2-inch tires, all models are shod with 34 by 4 tires, the wheels being second growth hickory with heavy spokes.



Upper—Detachable sedan top fitted to regular touring body on Kissel 42-six chassis. This combination sells for $2,000 and furnishes an admirable all-weather car

Middle—The four-door five-passenger touring body which lists at $1,650 mounted on the new six-cylinder chassis

Lower—With one-compartment touring body having two doors and carrying five passengers, the 42-six sells at $1,650

As usual, the company has made a strong feature of body design, the new models, which are all products of the Kissel shops, being true adaptions of the streamline principle. Body walls are of special sheet steel, with aluminum backs, covered with the best grade of leather, the cushions which are 11 inches deep, incorporating mattress springs and fine curled hair. The storage facilities are unusually ample, the compartment under the rear seat measuring 43 by 15 1-2 inches. Tools are stored under the front seats, the space being almost equally ample. The standard color is Kissel blue with a gold hairline striping finished with English varnish. All control instruments are mounted in a straight line on the dash, where they are illuminated by concealed electric bulbs. Fenders are crowned.

Left Drive and Center Control

Steering is on the left, an 18-inch wheel with inserted spider operating a split nut and worm fitted with adjustable ball thrust bearings. This arrangement is semi-irreversible. Control levers are in the center on the driver's right.

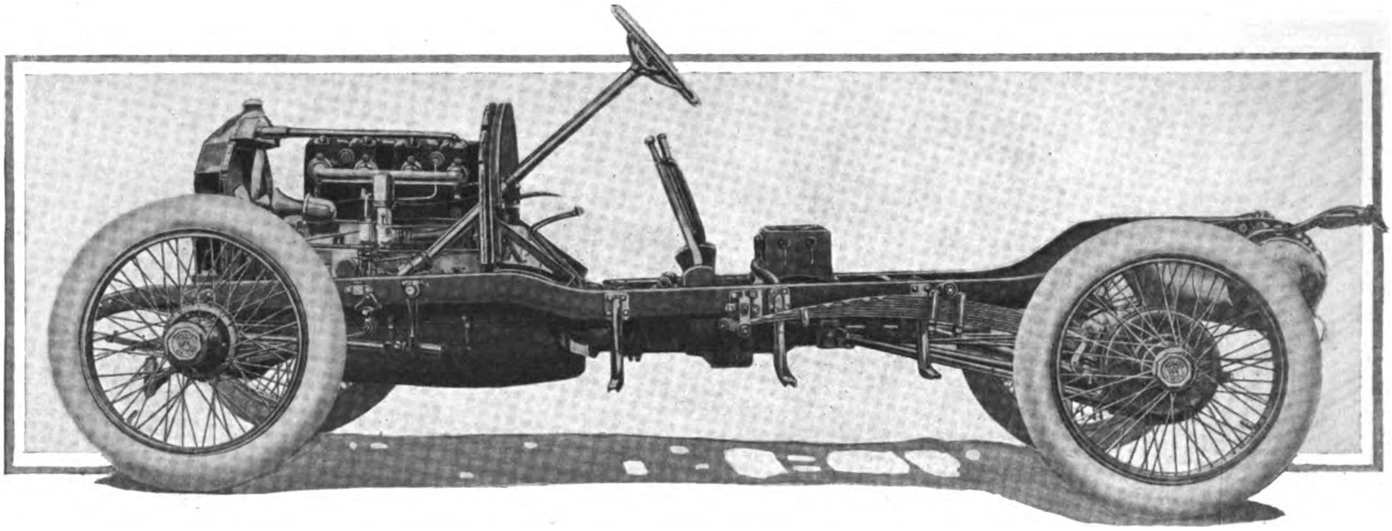
The equipment, which is included in the list price, includes a two-piece ventilating rain-vision windshield, one-person top with cover, demountable rims, Stewart speedometer driven by a gear from the rear of the gearbox, ignition lock, motor-driven warning signal, adjustable tire carriers and the usual jack, tools, foot and robe rails and tire repair outfit.

In addition to this new model, the Kissel company is continuing all its other models as follows: 60-Six, $3,150; 48-Six, $2,350; and 36-Four, $1,450.

B. S. A. Profits for Year $952,150

LONDON, ENG., Dec. 1—The annual statement of the Birmingham Small Arms Co., Ltd., also known as the B. S. A., the largest motor concern in England is always awaited by the British automobile trade with much interest, because, since the old Birmingham manufacturers have taken over the British Daimler works it has become one of the leading automobile manufacturing concerns not only on British soil but of Europe.

The fiscal year ending in 1914 shows a total profit of $952,150 equal to about 12.7 per cent. of the capital stock of the concern which is $7,500,000. A dividend of 15 per cent. has been declared, which with the exception of 3 years, is the same the concern has declared during the last 13 years. A quarter of a million dollars has been placed on reserve and $341,420 has been carried forward.



Side view of four-cylinder chassis of 1915 Willys-Knight, showing mounting of motor with its detachable cylinder heads, cantilever rear springs, left drive and center control, and also of horn and storage battery

Refinements Mark New Willys-Knight

Chassis Changes Include Addition of Tire Pump, New Carbureter and Use of Ball Bearings in Gearbox

THE most important change noted in the 1915 Willys-Knight made by the Garford Co., Elyria, O., is the reduction of the price from $2,750 to $2,475. The mechanical changes that distinguish the new model are in the details, the body lines have been improved, a four-cylinder, motor-driven pump has been installed, a Zenith carbureter added and ball bearings substituted for rollers in the gearset and rear axle.

Removable Cylinder Heads

Dimensions of the four-cylinder motor remain at 4 by 5.5 inches, giving a rating of 40-45 horsepower. The cylinder heads are removable and the return connections to the radiator are attached to the heads. The intake manifold is a simple T design. The carbureter is carried high on the left side of the motor so that the manifold is very short and the possibility of condensation negligible. A hot air pipe is fitted. Also on this side of the motor is the oil filler opening which is situated in the front arm of the crankcase and the oil gauge which is located in the rear motor arm.

On the right side of the motor are found the centrifugal water pump, tire pump and Simms magneto. The pump is placed at the front and the magneto to the rear, the latter being driven directly from the pump shaft. Between these two units is a gear which meshes with an idler driving the tire pump.

Force-Feed Oiling

The crankshaft is carried on five plain bearings and the eccentric shaft which drives the sleeves is mounted on three bearings. Oil is distributed to all the bearings by a force feed controlled by the throttle. A gauge on the cowl shows the pressure maintained in the system at all times.

The starting and lighting generator is a single unit U. S. L. system combined with the flywheel. Starting current is furnished by a 24-volt, 80-ampere hour storage battery mounted under the front seat. The generator is completely housed in a bell extension of the crankcase.

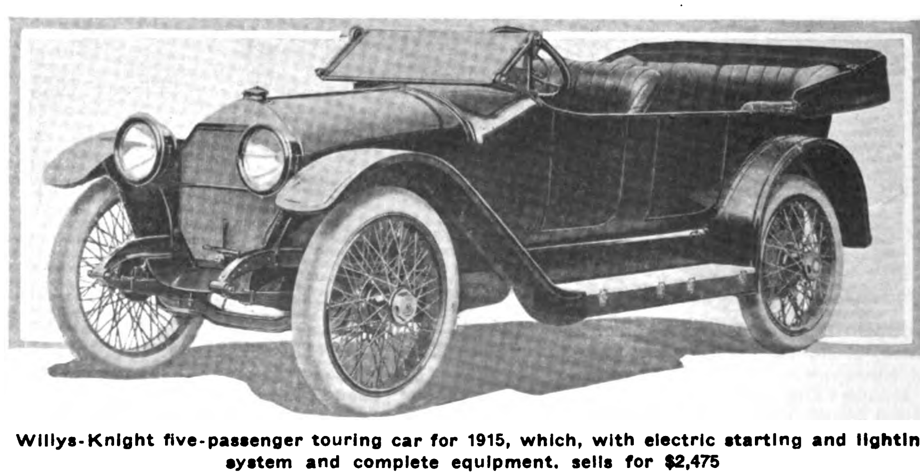
Power is transmitted from the motor to the gearset by a leather faced cone clutch with springs under the leather to insure easy and gradual engagement and a clutch brake to slow the clutch down when disengaged and thus facilitate gear changing.

Four-Speed Gearset

The gearset is a four-speed unit mounted amidships. Direct drive is on third. The gears have wide faces, it is stated, and are made from heat-treated vanadium steel. As previously noted, the gear shafts are now mounted on ball instead of roller bearings.

The rear axle is a floating type with worm driving gears. The worm is situated under the wheels so that it is continually submerged in oil thus affording maximum lubrication and minimum wear. This construction also gives straight line drive.

Two sets of brakes, both operating on the wheel drums, are provided. The service set are external contracting and the emergency internal expanding.



Willys-Knight five-passenger touring car for 1915, which, with electric starting and lighting system and complete equipment, sells for $2,475

The front axle is an I-beam drop-forging, being made in one heat without welding. Renewable bronze bushings are employed in the steering arms, ball thrust bearings in the steering knuckles and taper roller bearings in the hubs. It is stated that the steering knuckles are so designed that a very short turning radius is allowed.

Lanchester Rear Springs

In the rear, the Lanchester cantilever method of spring suspension is continued. This spring is an inverted semi-elliptic which is fulcrumed at its center to the frame and shackled at its forward end. The rear is carried under the axle where it rests upon a roller, permitting a free backward and forward movement and removing the dead weight of the spring from the rear axle, thus tending to improve the riding qualities of the car and to decrease the wear and tear on the tires.

Since the range of travel of the cantilever spring for a certain up and down movement of the axle is only about one-half the distance in the ordinary half-elliptic, the former moves up and down at a slower speed than the latter and the shocks to which the passengers are submitted are just that much less. The dimensions of the springs are 52 by 2.5 inches.

Semi-elliptic springs are used in front, these measuring 38.5 by 2.25 inches.

Left Drive and Center Control

Left drive with center control is standard. The steering wheel has a diameter of 18 inches and is a worm and full gear type. These parts are hardened steel and adjustable and are equipped with ball thrust bearings.

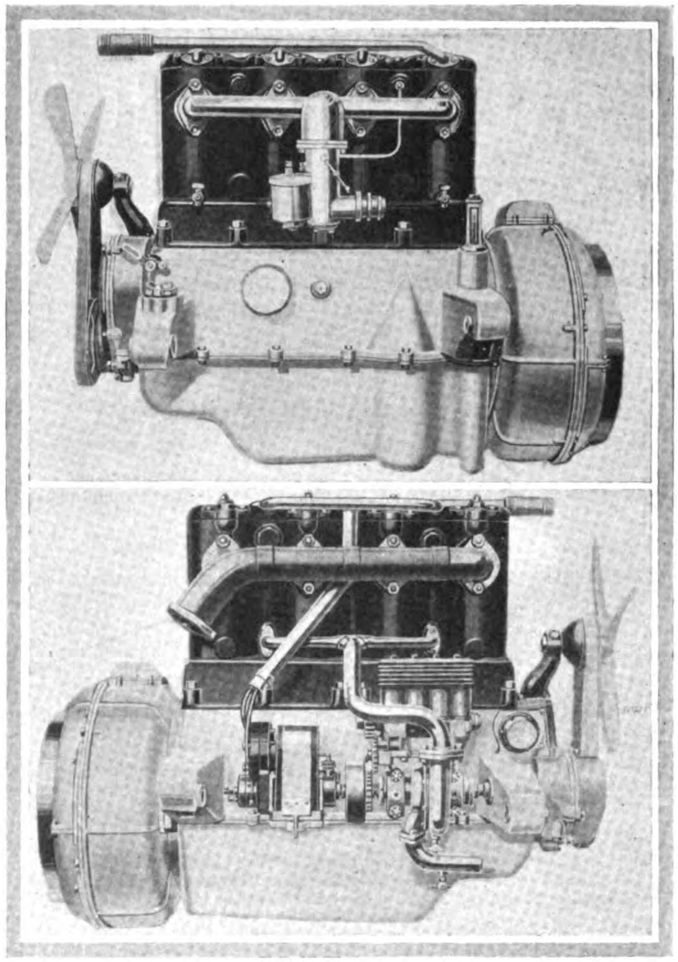
Turning to the body, it will be noted that the lines have been improved somewhat, giving the car a better streamline form. The body is composed of steel and wood, all hinges are concealed and the latches operate from the inside. The finish is dark blue with ivory striping, and the metal parts are nickel trimmed.

The new body furnishes an abundance of leg room for the tonneau passengers so that with three in the tonneau there is no crowding. The seats are extra wide. High seat backs and deep upholstery add to the comfort. Full Turkish roll cushions are used. The flexible springs in the upholstery are filled with selected curled hair and covered with long, straight-grained hand-buffed leather. The front seats are adjustable, permitting the position best suited to the driver.

New Instrument Board

An instrument board extending across the body under the upper edge of the cowl is a new feature on the Willys-Knight. This brings all of the indicating devices into a position just a trifle below the driver's ordinary line of vision. The electric light switches are also conveniently located and can be reached without effort. The electric horn button is placed at the top of the steering column.

The equipment includes complete electric starting and lighting equipment, one-hand extension mohair top with storm curtains and top boot, windshield of the folding type, inspection lamp, engine driven, four-cylinder power tire pump, speedometer driven from the gearset, electric horn, extra wire wheel and carrier, long tool boxes under the running boards, robe rail, foot rest, tire repair kit, jack and tools. Tires are 36 by 4.5 inches, fitted on quick detachable rims.



Upper—Intake side of four-cylinder motor used in Willys-Knight for 1915. Note high mounting of carbureter and housing for USL starting and lighting system

Lower—Exhaust side of motor, showing mounting of new four-cylinder tire pump, centrifugal water pump and Simms magneto. Also note neat method of wiring and strong fan attachment

200 Goodyear Family Homes Completed

AKRON, O., Dec. 14—After a year in the making, the plan of the Goodyear Tire & Rubber Co., of this city to provide modern homes for its workmen at actual cost, has made such progress that it is regarded as one of the interesting sights of the city.

Nearly 200 homes have already been completed and occupied and many more applications for homes will be acted upon as soon as the return of spring makes building operations possible.

President F. A. Seiberling, whose idea it was, bought several farms at the edge of town, not far from the works. A design for the community was arranged by an eastern landscape gardener. Streets were laid out in graceful curves, pavements and sidewalks, sewers and gas and water pipes, etc., put in, all on large contracts, and the total cost of the land plus the improvements was divided into actual lot prices, without profit. Then contracts for houses were let in large numbers insuring lowest costs, and the completed properties turned over to workmen and paid for as rent. No down deposits are required.

Individuality in Houses

One of the strongest features of the plan is that every house has individuality. It in no way resembles the usual "company house." Brick, brick and stucco and frame are included in the designs, of which there are dozens—and each has its proportions and style in harmony with the whole plan.

Men who have been prevented from owning homes because of inability to make "down payments," now become home owners. The community already has its church, school and stores.

It is expected that the community, built upon the hills just outside the eastern limits of the city of Akron, will finally contain about a thousand homes.

New York's Delay

WHAT is wrong with old New York?

Indianapolis built its speedway years ago, thanks to the enterprise of four Hoosier citizens, and has made good. Minneapolis, in the face of a national depression, is building hers for the Northwest. Chicago, where there has been continuous hesitation for the past 3 or 4 years, has at last fallen into line. Sioux City, Iowa, started 2 years ago and has made good. The Pacific coast has corralled everything in the speed record field. Even the South in Texas has made good. But, why New York? Here within a short radius is a population approaching 9,000,000, ample patronage for a flock of speedways. Here in New York, the cradle of automobile racing in America, there is a most noticeable dearth. The coveted Vanderbilt that was conceived and nurtured on Long Island has wandered to the Pacific, where the energetic Californians have taken pity on it. Why New York?

Light Armored Cars

FRANCE, as well as other belligerents, has learned that weight and height are the two big handicaps on armored cars, truly a page taken from standard automobile experience. Too much weight or armor plate consumes the good in the car. The armored car, as with many other devices is largely a compromise, a middle course between the heaviest armor that would withstand bullets and the lighter armor that allows speed and a factor of protection. But in this war speed is often more desirable than over protection, and so France in its latest fleet of armored machines, described in other columns in this paper, has aimed at high possible speed at the expense of over armoring. The wheels are left entirely exposed, as they offer the poorest target—in fact the enemy will generally endeavor to disable the gun. Light weight and speed reduce this possible danger, in that a swiftly moving car offers a much poorer target than a slower moving vehicle.

Ethics of Attack

SINCE 1910 the use of block cast cylinders has increased from 8 to nearly 68 per cent. notwithstanding the usual arguments launched against the practice for years by those who saw to it that their method of casting singly, in pairs or in threes was infinitely superior to the block method. In spite of these continuous charges the block continues to gain, and unquestionably when the figures for 1916 are compiled the percentage will be still higher. How long before some makers will be content to watch new developments take their place in the industry without the usual muck-raking methods, worthy of some crossroad political campaign, being followed by those concerns that do not believe in the new or who for manufacturing or other reasons are compelled to use the older designs for some time. Manufacturing ethics would dictate at least a passive policy, yet the events of the last 5 years reveal several instances of where a maker openly attacked a type of design that he intended to use the following season, but which he thought he was required to attack because it did not coincide with his present methods. How long?

The Boomerang

LITTLE did some unsuspecting maker or salesman imagine when he first gloried in the overcapacity ability of a motor truck that the day would not be far distant when the makers would as a unit have to actively campaign against such destructive practices. It is not 3 years since a big metropolitan buyer made it a requisite of the demonstration that each truck should carry 100 per cent. overload at approximately 50 per cent. over the rated vehicle speed. The fastest performer was given the initial order. Today the tables are turning and our makers are finding it necessary to institute a campaign, one platform of which is to prevent spring makers supplying to owners stronger springs for a truck than those originally fitted, the ostensible object of the owner being to fit stronger springs to care for more overload. Brass-band salesmanship may appear attractive for a single order, but it proves very costly when adopted by the masses.

Exports for 10 Months Ending October Total $21,241,860

20,262 Passenger Cars Valued at $17,888,351 and 1,309 Trucks Worth $3,353,509 Sent to Foreign Countries—Great Britain Is Largest Buyer

WASHINGTON, D. C., Dec. 12—The detailed figures of the imports and exports of automobiles and trucks during October and the 10 months ended October, together with figures for the corresponding periods of last year, were made public today by the federal bureau of statistics. The general figures were published exclusively last week in THE AUTOMOBILE. The figures are of particular interest at this time as showing the influence of the European war on our import and export trade. The complete tabulation appears herewith.

In October 672 commercial cars, valued at $2,286,964, and 732 passenger cars, valued at $768,387, were exported, as against seventy-nine commercial cars, valued at $129,506, and 1,697 passenger cars, valued at $1,663,716, exported in the same month last year. The exports for the 10 months ended October last were 1,309 commercial cars, valued at $3,353,509, and 20,262 passenger cars, valued at $17,888,351. During the same period in 1913, 857 commercial cars, valued at $1,480,646, and 21,872 passenger cars, valued at $21,614,434, were exported.

The imports of passenger cars increased during October. Last year for that month, twenty-nine cars were imported while in October, 1914, thirty-two were brought from the other side. Ten of these were from the United Kingdom, which led all the other countries.

Exports to Non-Contiguous Countries

WASHINGTON, D. C., Dec. 12—Figures have been compiled showing the exports of motor cars and parts to the non-contiguous territories of the United States during October and the 10 months ended October, together with the figures for the corresponding periods of last year. The figures show that in October a year ago three cars, valued at $2,536, and parts, valued at $82, were shipped to Alaska. There were no cars shipped to Alaska in October last and the parts shipments were valued at $321. During the 10 months' period the shipments of cars increased from twenty-six, valued at $24,549, in 1913, to fifty-four cars, valued at $60,703, in 1914, while parts shipments increased from $3,176 to $8,100.

Hawaii Takes 139 Cars in October

Hawaii received 139 cars from this country in October last, the value of which was $120,247, while in October a year ago 29 cars were sent to the islands, the value being $49,083. During the 10 months' period the shipments increased from 496 cars, valued at $861,005, in 1913, to 753, valued at $764,029, in 1914. Parts shipments decreased from $8,172 in October, 1913, to $7,874, in October last, but increased from $76,435 to $79,535 during the 10 months' period.

Shipments of cars to Porto Rico increased from twenty-seven, valued at $31,972, in October, 1913, to thirty-six, valued at $33,275, while parts shipments fell from $5,792 to $5,241.

During the 10 months' period the car shipments increased from 232, valued at $295,703, to 284, valued at $268,632, while parts shipments decreased from $71,895 to $58,358.

During October last 5 cars were shipped to the Philippine Islands, the value of which was $10,790, while in October a year ago the number was 69 and the value $83,474. During the 10 months' period the shipments declined from 550, valued at $687,300, to 360, valued at $371,541. Shipments of parts increased from $7,776 in October, 1913, to $8,768, but decreased from $57,586 to $43,893, during the 10 months' period.

Spring Maker to Work with Truck Builder

Will Decline to Increase Spring Suspension for Dealers or Owners Without Consent of Truck Manufacturers—To Prevent Overloading Vehicles

NEW YORK CITY, Dec. 12—Manufacturers of leaf and supplementary springs have been asked by the Commercial Vehicle Committee of the N. A. C. C. to co-operate with the Chamber in its efforts to discourage the overloading of motor trucks.

Attention of the truck makers having been called to instances in which dealers and truck owners have asked spring makers to increase the capacity of the rear spring suspension of trucks so that loads greatly in excess of the rated capacity of the chassis could be carried, a circular letter was addressed to spring makers in general, stating that the truck manufacturing members of the Chamber of Commerce almost unanimously deprecated such practice, which leads to overloading and consequent injury of the vehicle.

It was pointed out that the springs as originally built into the chassis are carefully proportioned to the axle, wheels, tires, and driving mechanism, which are guaranteed only for the factory rated load capacity, and that the substitution of stronger springs and the carriage of heavier loads causes unexpected stresses in these parts, with probable consequent breakages.

A number of spring makers already heard from have agreed to notify the truck manufacturer of any orders received from dealers or owners to increase the spring capacity of his trucks and to decline to fill such orders without his consent, as suggested by the N. A. C. C.

Annual Banquet for January 5

In connection with the Fifteen Annual Automobile Show at Grand Central Palace in New York, the National Automobile Chamber of Commerce has decided to hold its annual banquet at the Waldorf-Astoria on Tuesday, January 5, 1915, which is during show week. The Banquet Committee, consisting of Messrs. Hugh Chalmers (Chalmers), chairman; Henry B. Joy (Packard); Benjamin Briscoe (Briscoe); Chas. T. Jeffery (Jeffery); and Fred W. Haines (Regal), has promised some interesting and novel features.

Plantation Rubber Shipments for United States

NEW YORK CITY, Dec. 14—The English embargo on the shipment of rubber from the Far East is still in effect; consequently only a relatively small amount of it is afloat. Negotiations are now in progress which may result in the shipment of some plantation rubber from London to this city for the United States Rubber Co. and its subsidiaries. Arrangements have been made for the sailing of two ships, carrying the Dutch flag, direct from Sumatra to New York City, loaded with plantation grades of rubber for the above company. They are to leave the Far East this month. The steamship Hawaiian, of the Hawaiian-American Line, arrived in this port last week from the west coast of Africa with a cargo of rubber consigned to the Continental Rubber Co., this city.

As a result of the English embargo and the interruption of transportation earlier by German cruisers, the price of both plantation and Brazilian grades has advanced sharply. It is pointed out, however, that the price now is governed almost wholly by the manner of transportation. If satisfactory shipping facilities could be arranged, it is stated, the prices for both plantation and Para rubber would decline. The falling off in consumption in Europe has been pronouncd because of the war, and this country has been at least 15 per cent. below last year. The output of rubber, both in the Far East and in Brazil, has been large. If it could only be placed safely in the hands of consumers the supply would be materially in excess of the demand, which, of course, would bring prices down, as already stated. At the present time the stocks of crude rubber in the United States are comparatively small. There is plenty of it in England, but it is being held there because of the fear that if it is released it would find its way into the hands of manufacturers in countries with which England is at war.

A number of the large Akron factories are busy supplying large war orders for rubber goods. As a result the rubber stock market has become materially strengthened. Stocks have leaped from $6 to $45 a share.

Cocoanut Water as Rubber Coagulant

NEW YORK CITY, Dec. 14—An article appearing in the Daily Consular and Trade Reports states that an important discovery, it is claimed, has been made in the use of cocoanut water as a rubber coagulant. Millions of gallons of cocoanut water, which now runs to waste, can be utilized as a profitable by-product.

Details of the process are not now available, but it is understood that the cocoanut water is allowed to ferment for 4 or 5 days, after which it can be used immediately for coagulating latex. One to 2 ounces of the fermented liquid will coagulate 1 pint of pure latex. It is said to produce a better rubber than that procured from the present method of using crude acetic acid, especially so far as color goes, and clearer than that obtained from the cocoa-fermentation acid treatment.

Automobile Safety Devices on Exhibition

NEW YORK CITY, Dec. 13—The second annual safety and sanitation exhibition in Grand Central Palace opened today. There are 200 booths devoted entirely to safety devices and inventions. Among the safety devices are several for automobiles, namely, the Auto Signalite, a rear signal manufactured by the Auto Signalite Co., this city; the McNutt non-explosive gasoline can, McNutt Can Co., this city; the Matisse no-glare spherical paraboloid lenses and electric dimming devices, C. & A. Matisse, this city, and the elastic safety buffer, Douglass Mfg. Co., this city. There are also a number of accessories such as the Shaw one-piece wrench, J. Edward Dunn Co., this city, and the Recordograf, a tape recorder, for use in commercial car work, American Taximeter Co., this city. This company also shows a taximeter and a hub odometer, called the Transimeter. The Bristol Co., Waterbury, Conn., is manufacturing the Bristo patent safety set screws.

In the Exposition of Inventions such recent inventions as the automobile automatic turning headlight, patented by Charles S. Parcells, No. 1,091,532, March 31, 1914, and an automatic locknut and axle for vehicles patented by G. Huettner, No. 846,349.

Design for Made-In U. S. A. spirit that is being widely suggested

Automobile Securities Quotations

NEW YORK CITY, Dec. 15—On Saturday the Stock Exchange was re-opened after the longest recess in its history. On Monday it was announced that the market was open for tradings in all securities, upon which the already bustling activity increased at once. Nearly all the stocks showed slight gains over the quotations for last week and some were substantially higher. General Motors common went up 8 1-2 points and the preferred 3 1-2, Willys-Overland common gained 3 1-2, Maxwell stocks went up slightly and Reo Truck added 1-2 point. Studebaker common dropped and preferred gained 1 point. Of the tire stocks, Swinehart showed the largest gain by climbing from the 69 of last week to 87, or an increase of 17. Goodrich preferred went up 6 points and the common lost 1-2. Goodyear common added 5 points and preferred 1. U. S. Rubber gained 5.

Market Reports of the Week

MARKET prices this week were mostly steady. A few of the metals, however, rose. Both copper and tin saw a steady rise from Wednesday. Both electrolytic and Lake coppers rose $0.00 3-8 a pound while tin rose $1.85 per 100 pounds. Lead remained steady but quiet. Antimony is in moderate demand and weaker at $0.12. Cyanide potash came down $0.02 a pound. Sulphuric acid is meeting with a seasonable demand, and the market retains a steady tone. Cottonseed oil dropped to $5.68 a barrel this week, a drop of $0.13. The market for plantation rubber and fine Up-River Para, was firmer, but aside from this, the situation lacked new features. Consumers manifested little interest in the situation, being disposed, apparently, to use up some of the supplies on hand before purchasing freely.

Hood Tire Co. Is Organized

WATERTOWN, MASS., Dec. 12—The Hood Tire Co. has been organized as a distinct corporation to manufacture automobile tires in Watertown, Mass., instead of having the work done as part of the general production of the Hood Rubber Co. The latter company does a big business in all kinds of rubber goods, including tires, but it was felt that there should be a separate company formed for the tires so that it could be better developed. Charles W. Daily is president and treasurer and Herbert E. Ross and Robert Muir are the other officers. The new company's capital is $20,000.

LANSING, MICH., Dec. 15—The Reo Motor Car Co. has declared its regular quarterly dividend of 2 1-2 per cent. payable January 1 to stock of record December 19.

Unisparker Wins Medal for Kent

PHILADELPHIA, PA., Dec. 11—Arthur Atwater Kent, of the Atwater Kent Mfg. Works, Philadelphia, Pa., has been awarded the John Scott Legacy and Premium by the City of Philadelphia for the Atwater Kent Unisparker and ignition system. This medal and premium were bequeathed by John Scott, chemist, of Edinburgh, who in 1816 created an endowment to the City of Philadelphia directing the interest and dividends to be divided annually among "ingenious men who make useful inventions." In 1834 the city vested the award of this medal in the Franklin Institute of the State of Pennsylvania. This is believed to be the first time that this medal has been awarded to a manufacturer of automobile parts.

Both sides of John Scott medal, presented to Arthur Atwater Kent

Walker Absorbs Chicago Electric

Truck Concern Buys Factory and Business—To Make Three Passenger Models

With the Property Practically Complete Organization Will Go with Walker Co.

CHICAGO, Dec. 14—The Walker Vehicle Co. of this city, maker of electric commercial cars, has purchased the factory and business of the Chicago Electric Motor Car Co. maker of Chicago electric passenger vehicles, which concern suspended business in October of this year. The manufacture and sale of Chicago electrics will be continued, the construction work to be done at the plant of the Walker company and the sales for Chicago on the site of the former sales agency for these cars. With the transfer of property practically the complete organization including the factory and service men will continue with the Walker company, Gail Reid formerly secretary and sales-manager of the Chicago Electric Motor Car Co., taking the office of general sales-manager.

Under the name of Chicago electrics the Walker company will market three models known as Models 151, 152 and 153. Models 151 and 153 are rear seat drive, four-passenger limousines, identical except that in Model 153 the right front seat is revolving, while in 151 the front seat extends across the car and is stationary. These models sell at $2,650. Model 152 is a front seat drive, five-passenger limousine and sells for $2,850.

The Chicago Electric Motor Car Co. was organized in 1912 by the late Frederick J. Newman. It was reorganized in November, 1913, for the purpose of expanding the business and invading the commercial-car field. In October, 1913, arrangements were made to liquidate the entire business.

Hoosier Automobile Men Are Optimistic

INDIANAPOLIS, IND., Dec. 14—The industrial and financial situation in Indiana has clarified to an encouraging extent and automobile interests regard the outlook for the coming year as very encouraging. Manufacturers of motor cars, parts and accessories have taken an increased activity within the last few days and still further improvement is promised.

The money market is much easier than it has been for several months which has permitted a resumption of activity in many lines. Orders for war equipment from European countries has caused thousands of men to be put back to work.

In the rural communities there has been little complaint, for farmers have had a prosperous year, due to large crops. The only complaint has been of losses suffered in certain parts of the state through the foot and mouth disease.

Kalamazoo Co. to Build 200 Trucks

KALAMAZOO, MICH., Dec. 12—According to President F. G. Clark, the Kalamazoo Motor Vehicle Co. will build 200 trucks in 1915. During the first year of the company, which ended in September, the output was twenty-five trucks. President Clark declares that during the second year of the existence of the company it is planned to build 200 thirty horsepower, 1 1-2 ton trucks, similar in design to the first model, although with several minor improvements which have been adopted. For those who desire to combine a light and heavy truck in one vehicle the company has devised the use of a trailer which will carry 3 tons, giving a capacity of 4 1-2 tons per haul.

Goodyear Officers and Directors Re-Elected

AKRON, O., Dec. 12—At the annual meeting of the Goodyear Tire and Rubber Co., last week, the stockholders reelected the directors, F. A. Seiberling, C. W. Seiberling, G. M. Stadelman, F. H. Adams, P. W. Litchfield, H. B. Manton and J. P. Loomis—and the officers of the company were also reelected, as follows: F. A. Seiberling, president and general manager; C. W. Seiberling, vice-president; G.. M. Stadelman, secretary; F. H. Adams, treasurer; W. E. Palmer, assistant treasurer, and P. W. Litchfield, factory manager.

DETROIT, MICH., Dec. 12—The stock, machinery and equipment of the bankrupt Benham Mfg. Co., which made the Benham six cars has been purchased by the Frank Bros. Iron & Metal Co., Orleans and Grand Boulevard, for $4,500. The assets of the defunct company were estimated by it to be worth about $40,000 but the appraisers reduced this figure to $15,000. The Union Trust Co., receiver, has not yet disposed of the real estate. The Puritan Mfg. Co. was the purchaser of the repair parts, tools, jigs, drawings, good will and name of the Benham company.

Form Company to Make Searle Tube

NEW YORK CITY, Dec. 12—The Searle Unburstable Inner Tube Co. has been incorporated in New York State with the ultimate object of manufacturing the Searle Unburstable inner tube; the tube is an English product which was demonstrated in New York City but a few months ago. The plans of the company are not fully developed. The incorporators are two attorneys and Orson Kilborn, son of Horace M. Kilborn, of the National City Bank, New York. The capitalization is $400,000.

Lyons-Atlas Capital Is $1,500,000

INDIANAPOLIS, IND., Dec. 12—An increase in capitalization from $1,000,000 to $1,500,000 has been made by the Lyons-Atlas Co., of this city, which is preparing to market a new, medium-priced car. Experiments on the new car have been under way for several months and are nearly completed.

Sparks Elected Mayor of Jackson

JACKSON, MICH., Dec. 8—William Sparks, secretary and treasurer of the Sparks-Withington Co., was today elected mayor of this city by a vote of almost 2 to 1 over his competitors. Mr. Sparks was a representative of the Charter Club, an organization for the maintenance of good government in Jackson.

DETROIT, MICH., Dec. 12—Frank J. Mooney, sales and advertising manager, and Charles E. Buck, his assistant, have resigned from the Hupp Motor Car Co. Their successors have not been chosen. Mooney had directed the Hupp advertising for several years and some time ago assumed charge of sales, Buck becoming his assistant at that time.

NEW YORK CITY, Dec. 12—J. C. Nichols, Inc., 1671 Broadway, at present New York City distributor for Wheeler & Schebler, Indianapolis, Ind., has been appointed exclusive Eastern representative of the Disco Co., Detroit, Mich. He will distribute the newly perfected Disco electric lighting and starting system for Ford cars.

Co-operative Plan for Federal Truck Dealers

NEW YORK CITY, Dec. 14—A new plan to get co-operation among truck dealers in small towns has been made by M. L. Pulcher, general manager of the Federal Motor Truck Co. His idea is for them to consider the truck needs of their community and recommend to prospective purchasers the particular size and model of truck which tests have proved to be the best for the purpose.

DETROIT, MICH., Dec. 14—Charles Denby will take charge of the export sales department of the Hupp Motor Car Co. He recently resigned from the United States Diplomatic Service to take the above position. He was Consul General to Vienna, having left his post there on a leave of absence November 18, and arriving in this city on December 12 with his family.

NEW YORK CITY, Dec. 14.—The Dimond-Apperson Motor Co., 2000 Broadway, has been appointed Apperson distributor for this city and adjacent territory.

Zenith Elected Member of M. & A. M.

NEW YORK CITY, Dec. 14—At a meeting of the board of directors of the Motor and Accessory Manufacturers, held Friday, the Zenith Carburetor Co., Detroit, Mich., was elected to membership.

Third Used-Car Report Issued

Prices on 128 Makes of Gasoline Cars and 14 Electrics—General Response Throughout Country

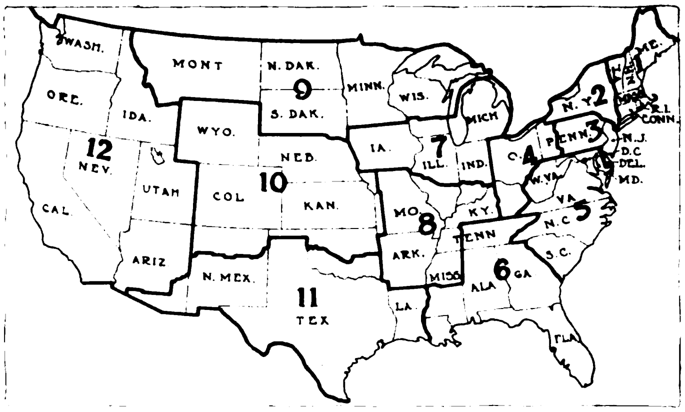
Improvements Planned for Next Issue —Trade Associations Promise Co-operation

CHICAGO, Dec. 14—The Chicago Automobile Trade Assn. has issued its third "Used-Car Central Market Report," which is the third edition since this work was taken up by the association. The prices in this issue are based on actual sales in the Chicago territory during July, August and September. Prices on 128 different makes of used gasoline cars and 14 makes of used electrics are included.

These reports on used cars have met with very general response throughout the country, the only objection thus far offered against the reports being a slight difference in market conditions in various sections of the United States, as compared with the Chicago zone. To correct this discrepancy the association has formulated a plan which is now being put into effect to collect sales data on used cars from different sections of the country with a view to compiling a national report. To collect these data the country has been divided into zones corresponding in area with those adopted by the Federal reserve banking system, and the trade associations within these zones are being asked for co-operation on the prices for used cars sold in the respective territories. A map showing the division of the country according to the Reserve Banking System is used as a basis of the work.

When this step from a local market report to a national one is taken the report pages will be altered, and will appear as in the illustration herewith which is a sample page inclosed in the current edition for the purpose of showing exactly how the national work will appear. The national report will be in the form of a booklet, 12 1-4 by 9. In the last column of each page on the national report will be published the "appraised as is value" for the Chicago zone only. This will be the only appraisement made, but a margin will be left in the book so that trade associations using the book can meet jointly and insert their local appraised value. The first issue containing the values as based on the zone system will appear in January and will be based on sales made during the months of October, November and December.

The work of collecting these sales data by trade associations in the different zones will not be a difficult matter and already several associations have notified the Chicago organization that they will co-operate in making this a national report.



Map of the United States, showing division into zones according to the Reserve banking system, used by Used-Car Central Market Report

Co-operative Garage for Electric Pleasure Cars

NEW YORK CITY, Dec. 12—The often-talked-of plan of a co-operative garage for electric pleasure vehicles has become a reality with the signing of a lease by the New York Electric Vehicle Assn., for a building on the southwest corner of Central Park West and Sixty-second street. A number of the leading manufacturers of electric pleasure vehicles are co-operating with the association in this undertaking. The Rauch & Lang, Detroit and Baker companies will have showrooms in the building, making it their headquarters. The various manufacturers will have their showrooms in the building and these are being rapidly fitted up for occupancy, while the garage itself is being equipped so as to make it in every way ideal for electric cars. It will start with accommodations for 150 cars, of which more than 100 have already been secured. It is planned there will be a fixed charge of $45 a month which will include battery charging, care of the car and taking the car to and from the owner's residence to the garage.

4-90 Five-Passenger Newest Chevrolet

NEW YORK CITY, Dec. 16—A new five-passenger touring car is announced by the Chevrolet Motor Co., New York City and Flint, Mich. It has a 20-horsepower, four-cylinder, valve-in-head type of motor, as conforms with standard Chevrolet practice. It is equipped with a magneto, 30- by 3-inch tires, 102-inch wheelbase and weighs 1,700 pounds, and lists at $490. It is called the 4-90.

It is stated that many special features will be found on this car which will be exhibited for the first time at the New York Show. These features include novelties in spring suspension, a steering gear mechanism, rear seat arrangement, clutch collar and hub cap. It is stated that double-acting, shock-absorbing springs, reinforced at the top and bottom of the center leaf are used and that the machine rides well and holds the road at all speeds. Patents have been applied for.

An unusually simple and light steering gear has been evolved. It is stated that it can be controlled with very little effort and that it will turn the car in a 20-foot circle.

A section of the back of the rear seat is removable, permitting the person occupying the center to relieve what is termed the hip-and-shoulder wedge. This permits a four-and-a-half-passenger car to be converted into a five-passenger car with a comfortable seating capacity. The car has an all-steel body with flush sides and concealed hinges with steel sills and door posts. A speed of 50 miles per hour is claimed.

To Continue Premier Cars

Business Good Under Receiver Smith, Who Is Elected Trustee —Creditors Are Optimistic

INDIANAPOLIS, IND., Dec. 15—Frank E. Smith, who has been receiver of the Premier Motor Mfg. Co., was elected trustee of this organization, at a meeting of the creditors before referee in bankruptcy Albert Rabb, here, and the manufacture of the Premier automobile will be continued.

The meeting developed the fact that the Premier is enjoying prosperity under the administration of Mr. Smith, more business having been done during the period of receivership, than in a similar period before the appointment of the receiver.

The Premier difficulties in the courts started on October 17, and since that time Mr. Smith had pruned down the organization, manufactured automobiles, sold them, and in various ways, profitably adjusted the financial affairs of the company, resulting in the successful building and distribution of the product.

That the Premier company will be allowed to exhibit at the Chicago show, carry on an advertising campaign, and bring out a new model car, in addition to the current models, were all brought up for discussion before the referee in bankruptcy and the assembled creditors.

Creditors stated that the plans, as outlined, would be carried out, as they would unquestionably show a profit, and might eventually bring the Premier back to its original, if not to a better position than it previously occupied.

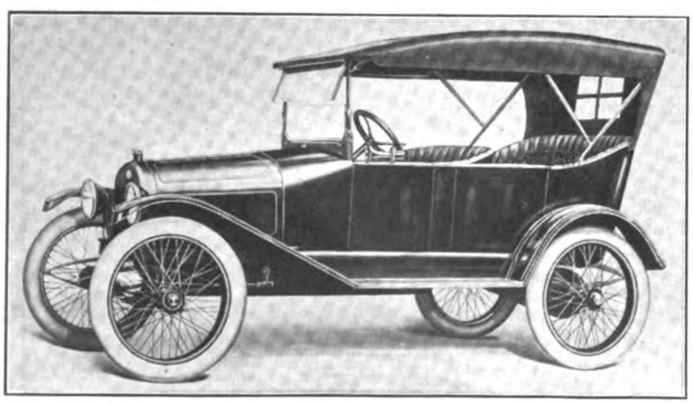
American Motors Discharged from Bankruptcy

INDIANAPOLIS, IND., Dec. 14—The American Motors Co. has been discharged from bankruptcy. The proceeding, a most unusual one, gives rise to what seems to be a well-founded report that V. A. Longaker and associates will soon announce plans for the return of the underslung type of motor cars to the market. Mr. Longaker when seen confirmed the court's discharge of the company from bankruptcy, but beyond saying he had no other announcement to make at the present time, he was quite reticent.

It is not unusual for individuals to receive discharges from the Federal Court in bankruptcy proceedings, but it is uncommon in the case of corporations and it was somewhat of a surprise when Judge Albert B. Anderson in the U. S. district court granted the discharge.

It has been known for a long time that someone would sooner or later revive the underslung type of motor car, such as was manufactured by the American Motors Co. During the company's embarrassment many overtures to revive the car have been made, but no one has been able to get inside plans. That at least 1,000 cars of the underslung type could have been moved from Indianapolis during the past year is believed to be a conservative estimate as a result of the many inquiries received.

The American Motors Co. was organized in Indianapolis in 1905. The plant was located in Indianapolis. It is estimated that between 3,000 and 5,000 cars of this type are now being run in the United States and Canada.



New Metz touring car selling for $600 with 105-inch wheelbase and Gray & Davis starting and lighting system

Stewart-Warner Denies Horn Patent Infringement

NEW YORK CITY, Dec. 15—Denying the charge that its hand-operated horn in any way infringes the Long hand horn patent No. 1,090,080, and claiming that the patent is invalid, the Stewart-Warner Speedometer Corp., of New York, filed its answer yesterday in the suit brought against it and the Stewart-Warner Speedometer Corp. of Virginia last month by Gottfried Piel and the G. Piel Co.

The Stewart-Warner interests claim that the Virginia corporation is not within the jurisdiction of the U. S. District Court for the Southern District of New York, in which the suit is brought, and their attorney will appear before the court Friday with a motion to dismiss the bill of complaint against it on that ground. On Friday the motion of the Piel company for a preliminary injunction will also come up.

In the answer filed by the New York corporation it is stated that its business is separate and distinct from that of the Virginia corporation and that its place of business at 233 W. Fifty-eighth street is not a regularly established place of business of the latter.

It asks for proof of the ownership of the Long patent and states that it is not true that the Stewart-Warner Speed-

Board of directors of Continental Motor Mfg. Co., Detroit, Mich. Left to right—B. F. Tobin, president and treasurer; R. W. Judson, vice-president; A. H. Zimmerman, secretary and assistant-treasurer; W. A. Fredericks, chief engineer; H. J. Warner, second vice-president; G. W. Yeoman, assistant to the president and director of sales

The Anderson Electric Car Co., Detroit, Mich., maker of Detroit electrics, has received orders from London for a number of buses similar to those already in use in that city. These buses, of the type illustrated above, are fitted with 60 A-8 Edison batteries capable of carrying the vehicle 50 miles on a charge. The capacity of each bus is thirty people ometer Corp. of New York has made or sold automobile horns embodying the alleged inventions of patent 1,090,080 and claimed in claims 4, 5, 7, 8, 9, 10, 11, 12, 13 and 14. The answer declares that the only automobile horn the corporation has been selling does not closely resemble the hand-operated horn made by the G. Piel company. It denies that the G. Piel Co. created the hand horn business and states that the Stewart-Warner corporation entered the business of selling hand horns in straightforward business competition and that it was aware of the constructions on the market, none of which, it states, closely resembles the Stewart-Warner warning signal.

The answer goes on to claim that the Long patent is invalid for lack of invention, lack of novelty, for excess and for aggregation, and avers that Long secured his patent with intent to defraud and deceive, the structure covered not being his own but that of A. Aufiero, who is now contesting Long's right to the patent in the Patent Office at Washington. In proof of its charge that the Long patent is invalid the answer cited seven men and firms beside Aufiero who, it states, knew and practiced the alleged invention prior to the alleged invention thereof by Long.

It also cites patents to the number of fifty-nine which, it alleges, embody the ideas of the alleged inventions in the Long patent, and which were granted prior to the latter.

The answer concludes by asking that the bill of complaint against the Stewart-Warner Speedometer Corp. of New York be dismissed with costs.

Metz Touring Car at $600

WALTHAM, MASS., Dec. 14—The Metz Co., this city, has placed on the market a touring car model selling at $600. It has a 105-inch wheelbase and elliptic springs. It is equipped with the Gray & Davis separate unit electric starting and lighting system. The streamline body has flush doors. The hood is tapering with a rounding top. Wire wheels, 32 by 3 1-2-inch, are used with Goodrich clincher tires.

The engine is water-cooled, with Bosch high-tension magneto and A. W. T. carbureter. The cylinders are 3 7-8 by 4, giving a rating of 24.2 horsepower and the valves, push rods and springs are completely inclosed. Other equipment includes a built-in gasoline gauge, speedometer, Hyatt roller bearings, signal horn, tire outfit, jack and tools complete. It has a fiber grip gearless transmission. According to the maker, the car is capable of 5 to 50 miles an hour on high.

More States Declare War Tax

NEW YORK CITY, Dec. 14—The States of Illinois and Ohio have ruled that all applications for registering automobiles and motor trucks, as well as applications for chauffeur's licenses, must bear the usual 10-cent Federal revenue stamp. This ruling will apply on all 1915 registrations.

The State of Maryland, through Collector of Internal Revenue Miles, who raised the point that state licenses are not taxable under the emergency war tax law, has received assurances from the department in Washington that that view is correct. Now that Federal authorities have ruled the collection of war taxes on New Jersey licenses invalid, automobilists don't know how to get their money back.

Refuses to Issue Kentucky Licenses

LOUISVILLE, KY., Dec. 12—Louisville automobile owners whose licenses are about to expire were thrown into a quandary yesterday when the Louisville Automobile Club was advised by the Commissioner of Motor Vehicles at Frankfort not to forward to Frankfort any applications for license renewals, owing to the refusal of Secretary of State Crecelius to accept the recent definition of his duties handed down by the Attorney General.

It was also made known that Secretary of State Crecelius had informed the automobile club that applications for automobile licenses sent to his office would be refused.

About 7,500 licenses, one-fourth of which are those of Louisville people, will expire January 1.

Car and Truck Registrations Steadily Increase

BOSTON, MASS., Dec. 5—The fiscal year for the Massachusetts Highway Commission, that controls the automobiles in the Bay State ended November 30 and the figures just compiled shows that motorists contributed a large amount of money to the state this year. The grand total reaches $965,669.59. That it did not go up closer to the million mark is due to the fact that the motorists showed greater respect for the law, and so while the total number of cars and drivers increased a great deal the fines this year were slightly more than in 1913. The fact that the increase in drivers was about 22 per cent. and the increase in cars 23 per cent. and the fines were nearly the same as a year ago is good evidence that motorists are getting away from the speed mania. The total amount for fees was $925,964.75 while in 1913 it was $803,196.51. The fines in 1913 totaled $39,043, and this year they reached $39,704.84. When the expenses of running the highway commission are deducted Massachusetts will have more than $800,000 for road maintenance of which $640,000 will be available for state roads and $160,000 for improving through routes that are under city or town control.

The registrations for the year totaled 77,246 motor vehicles. These figures include 8,236 commercial vehicles and thiry-nine cars owned by non-residents. A year ago there were 62,660 vehicles which included 5,948 trucks and 920 non-residents. The general increase was 23 per cent. for all vehicles and about 40 per cent. for commercial vehicles. The larger part of the cars registered were less than 30 horsepower and came under the $10 classification. As a matter of fact including the electrics and the trucks registered at $5 the number of vehicles paying $10 or less totaled 60,103 out of the 77,246. There was a gain of 180 in the manufacturers' and dealers' class. There are now 99,532 persons licensed to operate cars in Massachusetts, or about one in every 33. This is a gain of 18,488. The comparative figures for 1913 and 1914 appear herewith.

MADISON, WIS., Dec. 12—The state of Wisconsin's gross revenue from automobile and motorcycle registrations thus far in 1914 is $294,477, or nearly twice as much as was collected in 1913. On November 28 the total registrations by private owners at $5 each were 53,341; motorcycles, 7,876 at $2 each, and dealers, 1,202 at $10 each. It is expected that about 100 additional private owners' registrations will be made before December 31, when all licenses expire and must be renewed at the same price schedule. On January 1 the secretary of state predicted a registration of 45,000 private owners, but his estimate is already 8,341 wide of the mark. Applications for 1915 registrations will be received after December 15 and issued on January 1.

DENVER, COL., Dec. 12—Twenty thousand cars for Colorado in 1915 is the estimate made by Secretary of State James B. Pearce, who has just received his first consignment of license tags for the new year. The order calls for 19,000 regular tags and 1,000 dealers' tags. The total registration so far for 1914 is estimated at close to 19,000, but complete reports have not yet been received from the outside counties.

LANSING, MICH., Dec. 12—According to the figures given out by Secretary of State Martindale, there were 76,350 automobile licenses issued in Michigan so far this year.

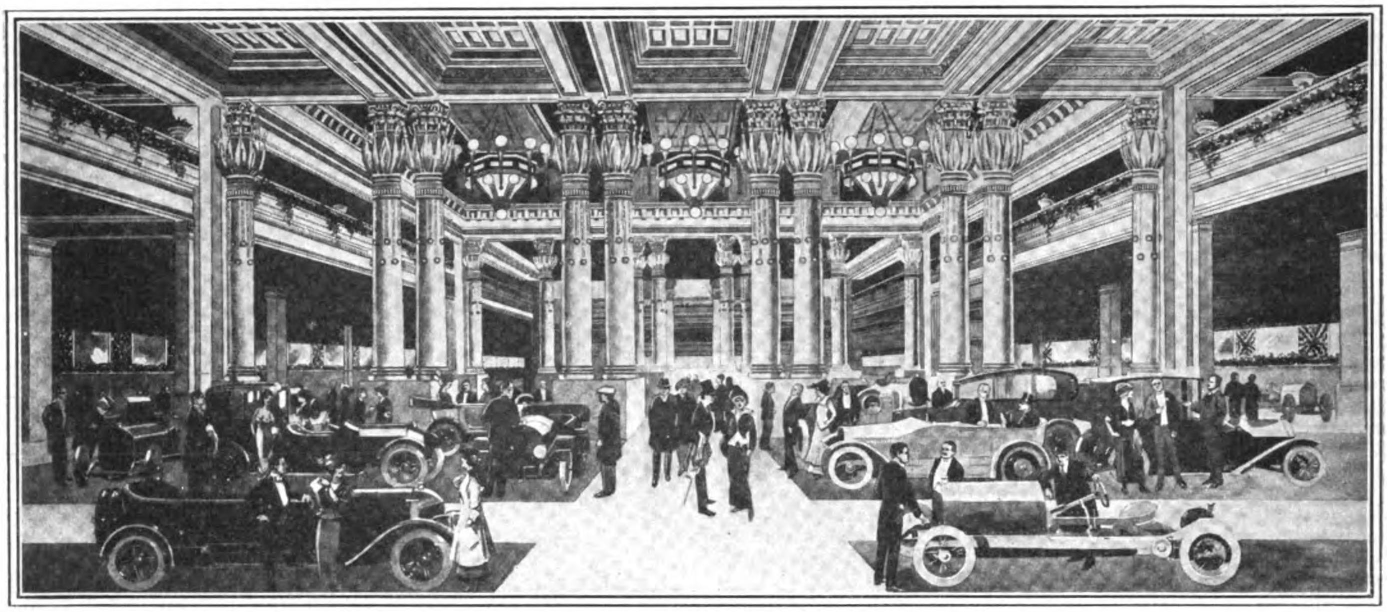
TORONTO, ONT., Dec. 7—Over 6,000 automobiles are registered as owned in Toronto which is more than are numbered in many of the principal countries of the world. It is interesting to note that 50 per cent. or half the cars sold in Toronto are Fords while 85 per cent. of all the cars owned by medical men and 90 per cent. of all the cars owned by commercial firms in Toronto are also Fords. Toronto's total figure according to a recent census is equal to the number of cars owned in the kingdom of Hungary and a greater number than are owned in British South Africa, Sweden, Switzerland, Holland or Bulgaria.

Massachusetts Car Registrations for 1913 and 1914

	1913	1914	Increase
Motor Veh. (Total)*	62,660	77,246	14,586
Commercial Veh.	5,948	8,236	2,288
Non-residents	920	39	†881
Motorcycles	7,127	8,161	1,034
Mfrs. and Dealers	1,330	1,518	180
Operators	17,009	21,257	4,148
Chauffeurs	5,233	5,601	368
Operator Renew.	40,858	51,090	10,232
Chauf. Renew.	17,934	21,584	3,650
Examinations	7,288	7,497	209
Fines	$39,043.00	$39,704.84	$661.84
Total receipts	$803,196.51	$965,669.59	$162,473.08

* Includes commercial vehicles and non-residents.

† Decrease due to new law making visitors register for all year.



Plan for the decoration of the main hall at the Grand Central Palace, where the New York Automobile Show will be held, January 2 to 9. The general scheme will be that of a Persian garden. Many mirrors will be used

Business Poor in Australia

War Affects Trade Conditions —Reduces Market for American Cars—English Small Cars Gain

Millions of Pounds of Wool Lying Idle —Crop Outlook Unfavorable

SYDNEY, AUSTRALIA, Nov. 20—Business throughout Australia has fallen off considerably owing to the extremely dry condition of the country, and this on top of the war has just about made trade in all lines as slow as possible and there seems little chance of improvement so far as Victoria and South Australia are concerned. New South Wales and Queensland have been more fortunate and they are experiencing an improvement, but the export of motor cars from America to Australia during the next 12 months will be on a very limited scale.

The English light car is making big strides throughout the whole of Australia, and in such cities as Melbourne and Adelaide the English light car is taking hold very rapidly, doctors and traveling salesmen purchasing them in quantities.

There are many factors which enter into trade conditions at present in Australia and in a recent compilation of opinions from leading bankers and financial men the following nine conditions are considered of varying importance in determining the present condition of affairs:

1. The government is the biggest employer in the state and it is putting its men on half time.
2. Extra taxation is foreshadowed by both the state and commonwealth and the spending power of the community is necessarily certain to be reduced.
3. Industrial corporations, although they have earned dividends during the past year, are not disposed to pay them due to bank restrictions, and also because of the future outlook.
4. Banks will no longer advance to store-keepers, but are throwing the burden upon wholesale houses. They will not advance to farmers as in normal times.
5. Wheat crops throughout the Commonwealth are bound to be of restricted character and it is quite possible that wheat will have to be imported to meet local requirements. Drought conditions are certain to prevail throughout Australia. The estimated loss of wheat on last year's values is 10,000,000 pounds.
6. The wool at present is commanding a good price for the very best quality which is scarce, and the cheaper grades have no value whatever. These were usually purchased by the Germans. Eleven million pounds of wool in New South Wales alone are lying without a market.
7. Building operations cannot be financed as the banks refuse to make advances.
8. Mines have closed down in many sections and cannot ship or sell concentrate.
9. The contribution of men and ships for the war will cost for the year $10,000,000 and the financing of this will have to be arranged for. The government proposes to place a local loan and this is leading banks to fear a depletion of their gold reserve. Paper money, it is thought, will be issued by the government and the sovereign will go to a premium.

Four Entries for Indianapolis Race

INDIANAPOLIS, IND., Dec. 12—With the contest yet 6 months away, four entries are already lined up for the next Indianapolis 500-mile race, the last to register being Ralph DePalma, America's road racing champion, with his Grand Prix Mercedes. Through his backer, E. C. Patterson, DePalma made entry this week, desiring to be as close to the head of the list as possible, because of the Hoosier elimination trials, which take place in the inverse order of nomination each year.

Though defeated at Corona, DePalma has great hopes of capturing the Indianapolis classic, since, out of all the machines that raced in the western contest, his was practically the only one conforming to the new 500-mile specifications, being well under 300 cubic inches, the limit prescribed by the speedway management, and tested in over 1,500 miles of actual racing.

A.A.A. Plan Annual Meeting May 17-18

NEW YORK CITY, Dec. 14—The American Automobile Assn. will hold a spring meeting at Boston, Mass., next year instead of a winter one. The Executive Board of the association decided at its December session in Washington, D. C., to postpone the meeting until May 17-18. At that time of the year the main highways in most of the states are in practical condition, and it has long been the opinion of many of the members that the annual gathering should be one to which one could tour over the roads.

At the conclusion of the Boston meeting it is quite probable that a party of transcontinental tourists will start for the Panama-Pacific Exposition.

Bull Tractor Sells for $395

MINNEAPOLIS, MINN., Dec. 14—It was stated in THE AUTOMOBILE for December 3 that the Bull tractor, which is manufactured by the Bull Tractor Co., this city, sells for $335. This was incorrect, as the price of the tractor is now $395, an improved design having been placed on the market.

A 2-Mile Board Speedway for Chicago

Contract Signed for Construction of Track for Speedway Park Assn.—315-Acre Site Secured—Contractor Gives $200,000 Bond to Complete Work June 1, 1915

CHICAGO, ILL., Dec. 12—After having built at least a half-dozen speedways on paper, it really begins to look as if Chicago is about to come into its own and that by the middle of next summer this city will have a track for automobile racing that will stand comparison with any in the country. This is the offering of the Speedway Park Assn., which announced today that it had placed the contract for the construction of a 2-mile board speedway to be completed by June 1 under the terms of the agreement.

The association was formed last June but purposely the organizers have refrained from publicity until all its plans had matured. The climax came last night with the signing of the contract for the actual construction of the track. The full title of the organization is the Speedway Park Assn., and the Speedway Park Club with headquarters in the Marquette building, Chicago. It has secured 315 acres of level ground situated on the west side of the city west of the Desplaines river between Maywood and Riverside, bounded on the north by Twelfth street, on the south by Twenty-second street, on the east and west by First and Ninth avenues and reached by nine transportation lines. Those who drive from the business section will have a fine 10-mile drive over boulevards.

The officers include: David F. Reid, a stock and bond broker, president; Charles McHugh and Harvey F. Harvey, vice-presidents, and Judson G. Hancock, secretary-treasurer. The directors are George W. McFatrich, Peter S. Thuerer, C. H. Stebbins, Jay F. Pitts, Joseph Hopp, John Irwin and John C. Roth, all prominent business men. Graham, Burnham & Co., are the architects.

The financing has been secured by means of a membership proposition. The full allotment of 1,000 members at $250 per has been secured, it is claimed, which put $250,000 into the treasury. In addition to that the directors have pledged $500,000, for which they will take stock if necessary. The lists having closed, it now is contemplated selling another 1,000 memberships at $50 a year which will not carry any stock.

The contract for the track calls for a minimum expenditure of $500,000 and with the maximum at $1,000,000. The contractor has given a bond of $200,000 to complete the work by June 1 and next week 500 men will be put to work on the property. Fortunately the land is vacant so no time will be lost in wrecking old buildings. Work will be continued all winter.

The track surface is to be 2 by 4's laid edgewise with 1-4-inch space between. The supports are to be of wood set at proper intervals upon concrete foundations or piers, the bottom of which will be below the frost line. The straightaway runs are to be pitched about 1 foot toward the inside. The north turn is to be figured for a maximum speed of 90 miles an hour. The south turn track level at the outer edge is to be the same level as the north turn, although the radii are not alike.

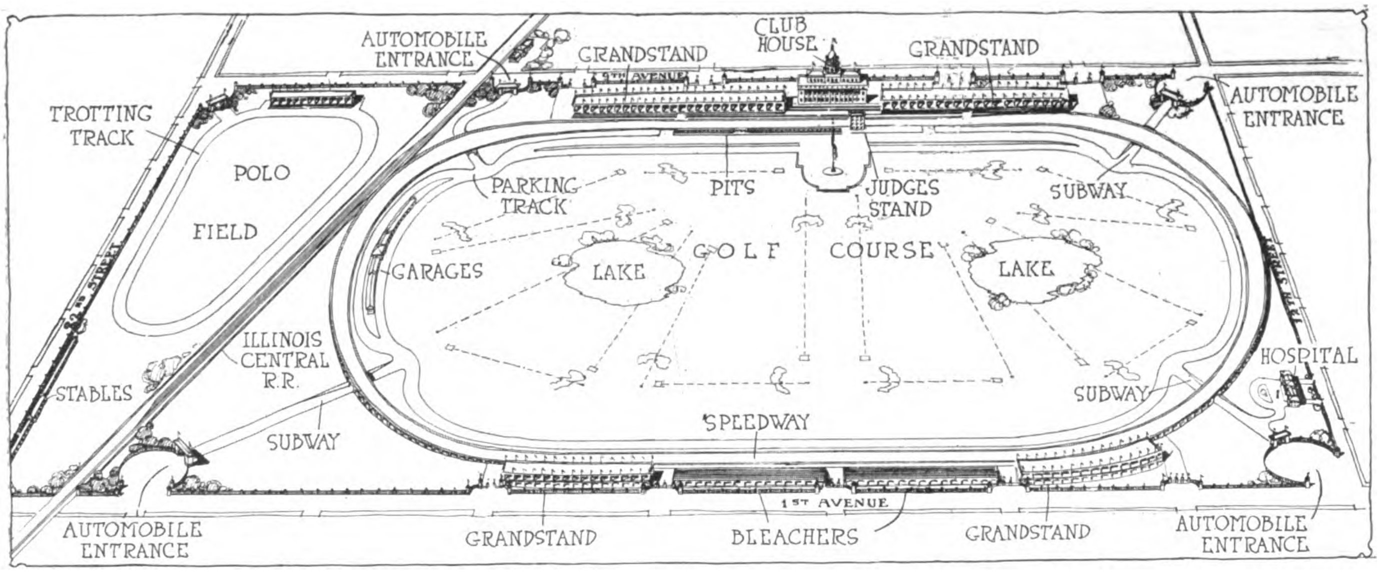
The track will be 60 feet wide on the homestretch and 70 feet on the turns. On the first turn there will be three different radii and the whole idea is to secure a speedway that will be safe and at the same time produce interesting competition. The backstretch will be 50 feet wide.

The race will be open to cars of a piston displacement of 300 cubic inches and under and will be for 500 miles. Qualifying trials will be for a speed of 85 miles per hour. The purse will be close to $50,000.

The speedway itself is not the whole issue in the proposition, for it also is planned to have golf links, polo field, aviation course and an equestrian course. The speedway itself will be built first.

Richard Kennerdell, chairman of the Contest Board of the A. A. A. spent today in this city in order to adjust the threatened conflict in dates between the new Chicago Speedway and the mile-track interests at Galesburg, Ill. Galesburg had been allowed June 16 as a sanction date for its $5,000 dirt track meet. The Chicago Speedway wanted this date. A compromise has been effected, Galesburg taking June 9, and leaving June 16 open for the new speedway. Chairman Kennerdell has insisted that the speedway authorities make reasonable progress in order to hold this date and has delegated Clifford Ireland, a member of the Contest Board, representing Illinois, to inspect the Chicago plant on February 1 to ascertain if sufficient progress has been made to warrant a possible meet on June 16. If such progress has not been made the sanction date will be cancelled. F. E. Edwards, technical representative of the A. A. A. contest board has signed with the speedway as contest manager.

At this date ten entries have been received for the Vanderbilt and Grand Prize races to be held in San Francisco, February 22, and March 1; the entries include three Maxwells, three Mercers, two Peugeots, and two Stutz. There is promise of an additional Stutz entry.



Plan of the 2-mile board speedway, polo field, golf course, etc., to be constructed by the Speedway Park Assn. and the Speedway Park Club at Chicago, Ill.

LANSING'S New Factories Cost $1,000,000—During the year 1914 more than $1,000,000 will have been spent in Lansing, Mich., in new buildings, and more than half is credited to the automobile industry. One company, the Reo Motor Car Co., figures on the list for over $400,000, and its total floor space is now 22½ acres. The new forge plant of the Atlas Drop Forge Co. is 675 feet long and 105 feet wide, and cost over $65,000. The new plant of the Capital Auto Body Co. cost over $40,000, and is one of the largest automobile body manufacturing factories in this state.

U. S. Tire Adds—The United States Tire Co., New London, Wis., will erect a four-story addition, 70 by 70.

Carbureter Plant for Dwight—Edward A. Atkins, Dwight, Ill., will establish a plant for the manufacture of a patented carbureter.

Peerless Starter Adds—The Peerless Air Motor Co., Stanfield, Ore., will erect a windmill factory at Stanfield, 50 by 100, of concrete.

Parker Purchases Trenton Bldg.—The Parker Motor Co., Trenton, Mich., has purchased the building and equipment of the Trenton Engine Co.

Shaw Adds $35,000 Bldg.—The Shaw Motor Co., Chicago, will erect a brick and concrete shop building, 60 by 108, to cost $35,000, at Prairie du Sac, Wis.

Bartlett to Build—The Bartlett Automobile Co., Stratford, Ont., of which C. Bartlett is manager, has had plans drawn for a factory to cost, equipped, about $50,000.

Full Force at Buick Factory—The Buick Motor Co., Flint, Mich., which several weeks ago reduced its working force, is now again working with its full force, or over 5,000 men. It is expected that the average daily shipments in December will be 140 to 150 cars.

Jeffery-Dewitt in New Field—The Jeffery-Dewitt Co., Detroit, Mich., manufacturer of spark plugs, has entered a new field, that of manufacturing high-grade small porcelain ware for the use of the plumbing trade. They expect to turn out 35,000,000 pieces within a year. European porcelain ware is no longer available.

Edison Battery Works Saved—Of the thirty-four buildings composing the plant of Thomas A. Edison, Inc., West Orange, N. J., three brick buildings and five or six of the new concrete buildings were destroyed by fire which started in the evening of December 9. The estimated loss is placed at less than $1,000,000. The laboratory and three other buildings, among them the one in which the storage batteries are manufactured, were saved. The primary battery building and all the structures in which the new phonographs, picture films and numbering machines are made were burned down.

Eureka Spring Wheel Establishes Plant—The Eureka Spring Wheel Co., Brockton, Mass., has been organized to put that device on the market, and the men backing it comprise Henry G. Martis, George S. Bent, John W. Barlow and James A. Case, of Brockton; Harvey D. Lincoln, of Attleboro, and Clinton Gowdy, of Springfield. The company has established a plant at 124 Court street there, and it is being equipped with machinery. The officials are displaying samples of the wheels in some of the larger Massachusetts cities. They state that by means of a series of springs taking the place of the ordinary spokes it is possible to use solid tires and get as good resiliency as from pneumatics at a great saving of expense.

Manufactures Automobile Upholstering—The National Car Equipment Co. has been incorporated at South Bend, Ind., to manufacture automobile top covers and upholstering of automobiles. The capitalization is $20,000. F. J. Cosgrove, of Chicago, is president, and Norman Roos, of South Bend, is vice-president. According to Mr. Cosgrove, the National Car Equipment Co. has taken over the Topeka (Kan.) Auto Trimming Co., and has moved the equipment to South Bend on account of better shipping facilities offered. The concern will start operations this week with a force of twenty-five men.

Metz's New $250,000 Plant—The Metz Co., Waltham, Mass., has just had finished for it a new plant covering 4 acres of ground which cost the company, with the land, a total of $250,000. It is now fully equipped with the latest machinery and the mechanical departments are now housed together so that there is no time lost in putting the cars together. All parts of the car are made here. The old plant is still in use and it will not be given up because the demand for the cars calls for all the space the company can secure. The new buildings are one story, with saw-tooth construction of roof, giving maximum lighting efficiency. Spur railroad tracks run to the factory, and during the past month the company has been making shipments in carload lots.

The Automobile Calendar

Dec. 12-19.......Akron, O., Show, Akron Auto Show Co., O'Neill Bldg.
Dec. 14-18.......Chicago, Ill., American Good Roads Congress.
Jan. 2-9.........New York City, Annual Automobile Show, Grand Central Palace.
Jan. 2-9.........New York City, Automobile Salon, Grand Ball Room of Astor Hotel, Automobile Importers' Alliance, E. Lascaris, Pres.

Aug. 20-21.......Elgin, Ill., Road Race.

The Week in  the Industry

Motor Men in New Roles

STRAUSS Elected Chairman — M. B. Strauss, of St. Louis, was elected chairman of the St. Louis (Mo.) section of the Electric Vehicle Assn. of America, C. A. Michel having resigned.

Madden Overland's Assistant Treasurer—E. S. Madden, credit manager of the M. Rumely Co., Laporte, Ind., will become assistant treasurer of the Willys-Overland Automobile Co., Toledo, O., January 1.

Now with the Stutz—S. Hardy Mitchell, formerly with the Cadillac agency in Boston, has bought an interest in the Stutz Motor Car Co., Boston, Mass., and he has joined the salesforce as assistant manager.

James Hood Tire Sales Mgr.—The Hood Tire Co., of Watertown, Mass., has opened a St. Louis (Mo.) office. L. S. James, formerly of the James Tire Co., of St. Louis, has been appointed local sales manager and agent.

Pardee Chicago Studebaker Manager—F. J. Pardee has become manager of the commercial vehicle department of the Chicago, Ill., branch of the Studebaker Corp. He was formerly a Pacific Coast representative of the F. B. Stearns Co.

Campbell Elected Mayor—Chester I. Campbell, secretary of the Boston automobile organizations, and the manager of all the big automobile shows in the Hub, was elected Mayor of Quincy, Mass., at the election held in that city last week.

Lempe Heads Albany Club—Dr. George G. Lempe was re-elected president of the Albany Automobile Club, Albany, N. Y., at the annual meeting. The other officers are: Vice-president, Peter G. Ten Eyck; secretary-treasurer, Roland Ford; counsel, Melvin Bender.

Portland Assn. Elects Officers—At the annual meeting of the Portland Automobile Dealers' Assn. in Portland, Me., the following officers were elected: M. B. Mank, president; W. B. Thombs, vice-president; E. E. Brewer, treasurer, and H. B. Chandler, clerk.

McGuinness's New Appointment—F. V. McGuinness, sales engineer of the Edison Storage Battery Co., Orange, N. J., has been appointed assistant manager of the railway dept., taking the position of W. F. Bauer, who was recently made manager of the company's Chicago office.

Langtry Heads Ogden Agency—The Cadillac Sales & Service Co., Ogden, Utah, has been organized to take care of the Cadillac interests in Box Elder, Cache, Rich and Weber counties. Headquarters have been opened at Washington avenue and Twenty-sixth street. E. M. Langtry is in charge of the company.

Greenwald Rumor Incorrect—In THE AUTOMOBILE for November 26 it was stated in these columns that Lemon Greenwald, Ashland, O., had been made manager of a branch of the Firestone Tire & Rubber Co., Santiago, P. R. This statement was an error on the part of our correspondent, as Mr. Greenwald is manager of the service department of the Firestone company, a position he has held for a number of years.

Barnes Promoted—W. H. Barnes, Seattle, Wash., distributor for G. M. C. trucks, has been promoted to Pacific Coast district manager for the commercial vehicles of the General Motors Co. He will spend 6 months of each year in Seattle and an equal length of time in San Francisco. He also will have supervision of the G. M. C. wholesale branch in California. With the promotion of Mr. Barnes the factory has decided to open a Northwest distributing branch in Seattle. Mr. Barnes has represented the General Motors Co.'s product in Seattle since 1909.

Recent Klaxon Changes—W. H. Bendfelt, formerly of the Detroit office of the Western Electric Co., and P. C. Little, of Boston, late of the Bi-Motor Equipment Co., of that city, have been added to the Klaxon selling organization. W. G. Packard, of the Klaxon service department, and until recently in charge of Klaxon service in Detroit, has been transferred to the sales department. He will work in conjunction with R. G. Coghlan in the Eastern territory. F. M. Hayes, who, for the past 2 years, has represented the Klaxon sales department in New England, will henceforward use his experience and knowledge of this territory in perfecting and extending the Klaxon service system there.

Garage and Dealers' Field

Plant Destroyed by Fire—Fire, November 12, destroyed the plant of the United Auto Co., Springfield, Mass. Loss, $20,000.

Lamp Branch Opened in Brooklyn—A Brooklyn, N. Y., branch of the Hudson Auto Lamp Works has been opened at 1054 Bedford avenue.

Detroit Gould Office Moved—The Gould Storage Battery Co., Detroit, Mich., has moved its office there in the Kerr Bldg., 100 Beaubien street.

Auto Surplus Moves—The Auto Surplus Stock Syndicate, 875 Eighth avenue, New York City, will be located after December 31 at Broadway and Fifty-second street.

Muskegon Vulcanizing Moves—The Muskegon Vulcanizing Co., Muskegon, Mich., has taken new quarters on Terrace street, and the latest in equipment will be installed in the plant.

Transforms Ambulances into Taxicabs—All the undertakers have disposed of their ambulances to the Ann Arbor Taxicab Co., Ann Arbor, Mich., which will transform them into automobile apparatus and operate them. They will be placed in service as soon as possible.

D'Arcy Spring in New Plant—The D'Arcy Spring Co., Kalamazoo, Mich., which manufactures springs for automobile seats, is occupying its new two-story, 200 by 300 feet, factory, and the finishing touches will be put on the plant before spring. The new factory of the company cost $50,000.

Ford Makes Improvements in Memphis—A permit for the construction of elevator inclosures in the new building of the Ford Motor Car Co., Memphis, Tenn., has been granted. The cost is given at $3,000, and, it is said, will bring the total amount of recent improvements to the building to more than $10,000.

Sparks-Withington's Display Board—The Sparks-Withington Co., Jackson, Mich., is supplying its dealers with a new demonstrating display board, which carries three hand-operated Spartan horns. The board is constructed of quartered oak, finished in the early English style, and carries the names and prices in plain view of the three models displayed. These are the Model EB, finished in black with nickel-plated front section of bell; Model F, in black satin finish, and Model M, with black satin body and interior of the bell nickel-plated.

Detroit Agent Builds Garage—A two-story showroom, office and garage will be erected at 694 Woodward avenue, Detroit, Mich., for the McKenney-Devlin Co., distributor for the Detroiter, Haynes and Grant cars. The showroom will be 50 feet square and two stories high, and fitted interiorly like a Dutch house. It will have a red tile floor and a large brick fireplace in the rear wall. Heavy oak beaming extending from the floor to the ceiling the full two stories in height and across the ceiling will be a feature. The garage will be 50 by 100 feet in dimensions. The service station at 22 Alexandrian street will be continued.

New Scheme for Automobile Sales—A new departure in the automobile world, which is interesting alike to dealers and buyers, has been inaugurated by C. E. Herrick, Inc., San Francisco. This firm will specialize in making cash purchases of medium-priced machines for buyers who desire to pay down a smaller sum than the ordinary dealer would be able to accept and to complete their purchase in reasonable monthly instalments. "Our plan will enable the dealer to make cash sales of cars that he would otherwise be obliged to sell on the instalment plan," said C. E. Herrick, "and it will enable many prospective buyers to obtain cars on terms which the dealer would be unable to offer them."

New Indianapolis Agencies—Several new agencies have been opened in Indianapolis. The Alter Motor Sales Co., distributor for the Alter, has moved its headquarters from Marion, Ind., to Indianapolis. A branch will be maintained at Marion. An agency for tubes and tires manufactured by the Hood Rubber Co., Watertown, Mass., has been opened at 514 North Capitol avenue by Clem T. Strauss. The Hampton Mfg. Co., manufacturer of Kant-Blo interliners, has established a sales agency at 429 North Meridian street, with W. F. Winslow as manager. The company will vulcanize free all tires and tubes blown out or punctured that are equipped with the interliners.

Accessories for the Automobilist

NO-SHAMMY Utility Box—A box for storing substances which need protection from air and dirt is made by the No-Shammy Products Co., Cleveland, O. The interior is divided into four parts, Fig. 1, three of which are round and one of which is rectangular. One compartment is intended for white lead, one for graphite and one for shellac. The large rectangular compartment is for grease.

In most garages these various articles are kept in the original containers and, although they may be used frequently, they are not always in good condition. The lead may be dry, the shellac thick and dirty and the graphite dry and flaky. The Utility box avoids all this. The box is made of heavy black japanned tin. The grease compartment is fitted with a self-closing cover, and the covers to the other compartments are furnished with hangers, so that they will not become lost.

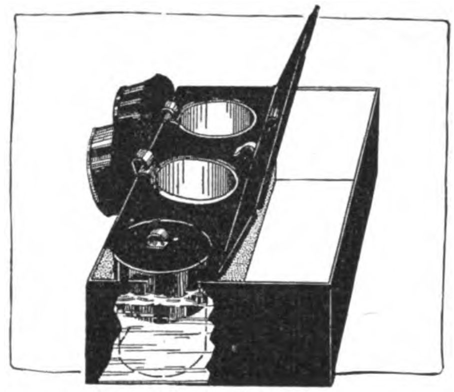

Fig 1—No-Shammy utility box

St. Louis Magnetizer—To recharge magneto magnets, the St. Louis Electric Works, 5409 Easton avenue, St. Louis, Mo., has put out the device shown in Fig. 2. It consists of a powerful electro magnet mounted on a neat wooden base, on which is a switch and two binding posts. A well-charged, 6-volt storage battery is connected to the binding posts, and the ends of the magneto are placed on the tops of the coils. The magnetizer weighs 8 pounds, measures 7 by 4.5 by 5.25 inches and sells for $7.50.

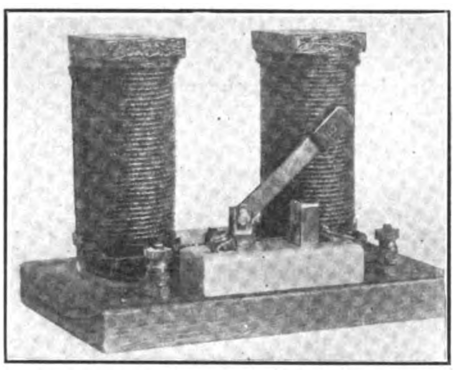

Fig 2—St. Louis Magnetizer

Ideal Electric Vaporizer—To provide easy starting in cold weather is the object of the new primer, Fig. 3, made by the Ideal Brass Works, Tenth and Canal streets, Indianapolis, Ind. There is an electrically-heated plug which is placed in the manifold and through which gasoline is discharged. Since the end of the plug is warm the fuel is heated and vaporizes easily, thus giving a good mixture and insuring a quick start. Current is supplied by four dry cells and the gasoline is supplied from a small gravity primer mounted on the dashboard. The device retails for $5 ready for installation, less batteries.

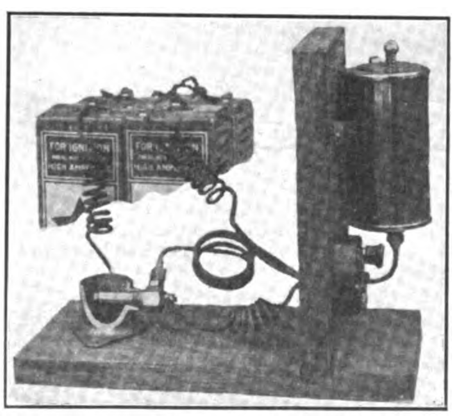

Fig. 3—Ideal Electric vaporizer

Jaeger Nitro Electric Lamps—Nitrogen-filled electric light bulbs which, it is said, give a white, intense light with a consumption of .5 watt per candlepower are made by H. J. Jaeger Co., Hoboken, N. J. A bulb is shown in Fig. 4.

The filament is made of drawn tungsten wire coiled into a helix and mounted within a very small space, thus concentrating the light and permitting close focal adjustment. Instead of operating this filament within a vacuum as is the case with the ordinary tungsten bulb it is surrounded by nitrogen and other inert gases under pressure, the presence of which permits a higher incandescence of the filament without disintegrating it, thus producing higher candle power and twice the efficiency of the ordinary type, it is stated.

There are two standard types, the G 16, 24 and 32 candlepower and the G 12, 15 to 21 candlepower. Both these lamps are for focusing and are made for voltages ranging from 6 to 14.

Davis Gas Lighter—An acetylene gas lighter has been put on the market by Hermann Dinkelaker, 7 N. Alabama street, Indianapolis, Ind. All that is required to light the lights is to turn a handle and press a button. In the city the lights may be dimmed by operating the same handle. The price is $5.

Presto Electric Hand Lamp—A simple lamp attachment which bolts to the top of a dry cell and which sells for $1.25 with battery has been brought out by the Metal Specialties Mfg. Co., 736 Monroe street, Chicago, Ill. As illustrated in Fig. 5, it consists of a bracket which may be attached to either the flush or extended carbon type of dry cell. The bracket is bolted to the carbon binding post and a wire runs to the zinc. There is a suitable handle for carrying the lamp by. The lamp itself is pivoted so that it may be set at any angle, thus providing most effective illumination.

Fisher Rim Grip Sub-Casing—The Western Auto Sub-Casing Co. Inc. of 1044 So. Los Angeles St., Los Angeles, Cal., is making the Fisher Rim Grip Sub-Casing, which is a casing used under the regular tire. The Sub-Casing is made of the same rubber impregnated fabric or friction as is used in all pneumatic tire construction. Varying numbers of layers of fabric depending on the size of the tire are built up and vulcanized together without any loose ends or overlapping splices.

Then two flexible flat steel bands are vulcanized into the Sub-Casing, one on each edge. These bands form the anchor or security for the reinforcement. Inflation of the inner tube forces these bands against the tire beads effectually preventing any slipping of the Sub-Casing which would be injurious to both tire and inner tube. These bands might be compared to the hoops on a barrel and the manner in which they hold the staves in place.

The Fisher Sub-Casing, it is claimed, is so strong and the basic principle is so practical that it holds all the inflation pressure strains put on it by the inner tube.

When used in tires that have unbroken fabric walls the makers guarantee against blow-outs, rim-cuts and other tire expense.

Pillsbury Wautopail—The Pillsbury Mfg. Co., Minneapolis, Minn., is manufacturing a water pail made of canvas and which can be folded and placed under one of the car seats. The fact that it can be flattened out makes this accessory valuable for those who do considerable touring. The Wautopail weighs but 8 ounces.

Nobody Home

What's the matter with the starter anyhow?

Nothing, your battery is frozen to death, that's all. Take it out, give it a decent burial and put in a Willard.

Then you can stay in the front seat, push the button and let her buzz! She'll turn that old engine over so fast it will make your head swim.

Somebody Home

There's always somebody home in the Willard Shops. Somebody inspecting every grid; somebody rejecting those "good-enough-for-some-folks" oxides that fall below Willard standard; somebody watching every man, machine and operation. It's all these little things put together that mean good hot service in cold weather.

ANSWER—Willard on the job in 85% of all electrically equipped cars.

Willard STORAGE BATTERY

Willard Storage Battery Company

CLEVELAND, OHIO

New York Branch: 228-230 W. 58th St. Detroit Branch: 736-740 Woodward Ave.
Chicago Branch: 2524-30 S. Wabash Ave. San Francisco Branch: 821 Monadnock Bldg.
Indianapolis Branch: 318 North Illinois St.

Service Stations in All Principal Cities in the United States, Canada and Mexico

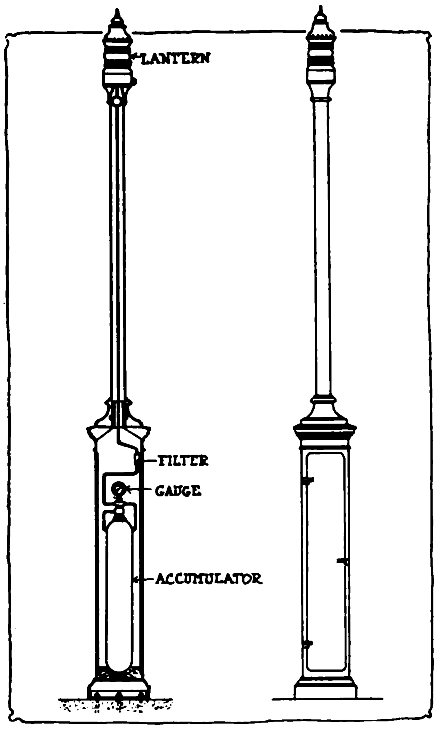

Fig. 6—A. G. A. highway beacon

Rubber Co., Chicopee Falls, Mass., is making a non-skid tire with a red top and white side walls for Ford cars. The tread has additional thickness and will therefore give greater life, it is stated.

A. G. A. Highway Beacon—A safety device, Fig. 6, to prevent accidents at night at dangerous turns, cross roads or railroad crossings, has been brought out by the American Gas Accumulative Co., Penn Building, Philadelphia, Pa., which has recently placed on the market a safety device known as the A. G. A. Highway Beacon, which is equipped with an automatic flash light giving from 30 to 90 flashes per minute, as desired.

It is evident that by using a flash light this danger signal cannot possibly be mistaken for an ordinary street light.

The illuminant used is dissolved acetylene, the brilliant white light of which makes it eminently suitable for a night signal. The acetylene is stored under pressure in seamless steel containers known as gas accumulators, which are made in various sizes from 2 1-2 to 1000 cubic feet capacity. These accumulators are filled with a mass of about 80 per cent. porosity. This mass is saturated with acetone, a liquid possessing the property of dissolving 250 times its own volume of acetylene at a pressure of 10 atmospheres.

As the accumulators are filled with a quantity of acetone equal to 40 per cent. of their own volume it follows that these containers will store 100 times their own volume of acetylene when charged to a pressure of 10 atmospheres.

The gas consumption is very small, approximately 0.8 cubic feet per 24 hours, and the light will burn for a period of from 60 to 200 days on one charging, depending on the size of tank.

Fig. 7 illustrates a highway beacon, recently installed in Potomac Park, Washington, D. C., which is equipped with a tank that will keep the light burning for 100 days at a total cost of $1.35.

Westinghouse Motor-Generator Battery Charger—The small motor-generator set, Fig. 8, forms a convenient, economical and reliable means for charging automobile starting, lighting and ignition storage batteries.

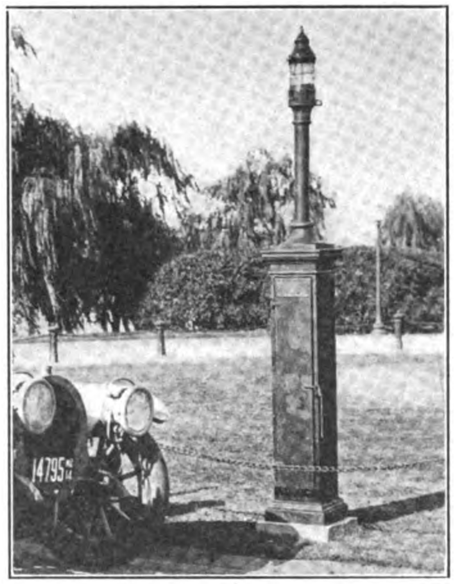

Fig. 7—A. G. A. highway beacon

It consists of an alternating-current motor and a direct-current generator compactly mounted in the same frame. The motor operates from the 60 cycle, 110 volt alternating current lighting circuit and drives the generator which furnishes the current for battery charging.

The generator is rated at 10 amperes and it can charge one or two 6-volt batteries or one 12-volt battery. Its voltage can be regulated from 6.3 volts to 12.6 volts by means of a field rheostat.

The operation is very simple. Merely connect the motor lead to the electric light socket and turn the snap switch. Adjust the generator to the desired voltage and connect with the battery. No attention or voltage regulation is required during charging. The generator is so wound that its voltage rises automatically at the end of the charge so that each cell receives 25 volts.

The length is 19 inches, width 7.75 inches, height 8.375 inches. Shipping weight 140 lbs.

The set is manufactured by the Westinghouse Electric Mfg. Co., East Pittsburgh, Pa.

Detroit Universal Coupling—The ball bearing universal which was briefly described in the October 29 issue of The Automobile is now being manufactured. The universal Products Co., 518 Woodbridge street, East Detroit, Mich., is the maker. The universal is shown in Fig. 9.

The features claimed for this universal are its frictionless action, perfect lubrication, capacity for frictionless longitudinal movement and its adaptability to tubular shaft drive construction which is now becoming so common.

It is stated that it is not only lighter than the usual type of universal but much smaller in diameter, contains less than half the amount of parts and is much stronger in proportion to its weight on account of its pressed steel body construction which eliminates the need for an outer housing.

The operation of the joint is clearly shown in the figure where it and it will be noted that the stress is taken by two hardened steel balls ground to very close limits and traveling in longitudinal races of circular section. These races are also hardened and ground to the proper limits of clearance to allow perfect rolling of the balls. The balls themselves are mounted on a hardened and ground nickel-steel trunnion pin which in turn is mounted through a third ball attached to the end of the drive shaft.

The universal action is obtained by the rotation and sliding of the ball members on the trunnion pin about the center of the spherical drive shaft head as a pivot. Moving the drive shaft up and down will cause the balls to roll in the races in opposite directions about the center while moving the drive shaft at right angles to this former movement the pivotal action is that of pivoting the trunnion pin through the balls themselves. The movement is limited by the conical, flat compensating spring at each end of the shaft, the shaft floating between these two springs.

Peerless Radiator—Hot water heaters which may be placed in the car floor in both the front and rear and which take their water supply from the radiator are made by the Peerless Radiator Co., Gibbs, Ida. Six tube heaters sell for $35, eight tube ones for $40. The connections to the water system are made near the radiator and do not interfere with cooling.

VOL. XXXI NEW YORK—THURSDAY, DECEMBER 24, 1914—CHICAGO No. 26

The AUTOMOBILE

Forces at Work During 1914 —The Year Review

Industry Grows In Spite of Financial and Industrial Depression —Epoch-Making Forces Launched—Conservative Activities a Characteristic—Factory Additions

DURING the year just closing the automobile industry has made most material progress, notwithstanding the financial and industrial depression which has settled more or less uniformly over the entire country. This continued prosperity, in the midst of general retrenchment, can only be attributed to the part the automobile is playing in business and private life, testifying to the fact that no longer can the automobile be considered a vehicle of luxury for the classes, but it must be interpreted as a vehicle of necessity for the masses.

Healthy Condition Country-Wide

THIS premise is based on the fact that the healthy condition has been generally country-wide, with the sole exception of those cities or localities where local conditions have been dominating factors.

Industrial and financial prophets told how on the outbreak of the war the automobile industry would suffer more than older established industries, industries that played a more useful rôle in carrying our great nation along on the highway of destiny, but the records since that memorable Saturday, July 30, show that the automobile industry is not a youngster, not a luxury, not a sunny-day industry, but that already this dominating industry of the twentieth century has taken a high place in the gamut of national importance, a position so necessary that even the restrictions brought about by the great war have not laid it low, as was anticipated; rather the automobile industry bids well to once more demonstrate that since its inception each succeeding year has been a bigger one than its predecessors, and that this is at least one industry that has grown from year to year, notwithstanding adversaries in the shape of industrial and financial misfortunes.

Industry Unequally Affected

ALL branches of the industry have not prospered to the same extent, those divisions that have appealed to the masses with special fascination having suffered least by war and financial and industrial stringency. The passenger car industry suffered less than the motor truck department, business houses from the opening of January evidencing more or less distrust, due unquestionably to the general state of national unrest and expectancy, based on how the varied governmental changes were going to work out. The passenger car market opened and continued active until the war cloud gathered, after which date trade in the higher-priced vehicles fell off most perceptibly, but business in the lower-priced types continued with amazing steadiness. The abundant cotton crop in the South with the poor market developed a condition local to cotton-producing states, which has prolonged itself to the present, when there are symptoms of general invigoration throughout that territory.

The accessory market has kept pace with car and truck production, but since August 1 general buying has been below par, a condition explained in many cities by the conservative money atmosphere, and in our larger cities because many automobiles were placed in winter storage months earlier than in previous years.

For several months the attitude of banks in many cities of nearly every state in the Union has not been conducive to business optimism, particularly with the dealers. Not a few banks have been slow to advance funds to dealers in payment for automobiles shipped on bills of lading, these banks apparently considering it a poor risk to make advances of this nature with automobiles as collateral. In some sections there appeared to be a concerted movement among certain banks to discourage dealers' business. Many banks consider advancing money in payment for unsold cars a poor risk, but modify their decision in nearly every case, namely, that the financial and business career of the dealer is invariably a factor to be considered. At the other end of this banking attitude are those factories desiring to raise funds from banks to pay for raw materials to be used in the manufacture of automobiles on which deposits have already been placed by the dealer. Refusing to assist the dealer in his purchase of cars and further refusing to aid in financing the maker has worked not a few hardships, but, thanks to a general movement intended to improve these conditions, it is anticipated that few serious damages will result.

Patent Litigation Continues

IT has become historic with the automobile industry to link with it an almost endless trail of patent litigation, a trait of character bestowed on the industry through Selden litigation before it was out of its swaddling garments. Three years ago when the Selden case was settled it was anticipated that this demoralizing dissension had passed, but nearly every month of the present year has witnessed new activities in the courts. Throughout the season litigation on electric motor horns and hand-operated horns has been fought with the keenest edge, and only recently has it appeared that the end was in sight and that both makers and dealers would have this nightmare eliminated. These fights have been carried through the local courts, through the courts of appeal and through the various divisions of the patent office, and the end is not yet.

Kardo Patent Situation

MORE industry-wide litigation was launched in March with the organization of the Kardo company controlling patents on floating axle, front axle and other constructions. So broad has this conflict become that the national organization, the National Automobile Chamber of Commerce, Inc., has not only conducted a comprehensive investigation in this country but also in Europe on the patent situation as affecting these lines, and at its last meeting decided to fight suits against any of its members on these patents, the validity of which has yet to be established in the courts. There have been some other important decisions handed down during the year, one in favor of the Hess-Bright company on bearings, another declaring the Knobby tire patent invalid, a decree forbidding the refilling of Prest-O-Lite tanks, and one in favor of the Motometer.

S. A. E. Activities Broaden

OUR national engineering society, the Society of Automobile Engineers, has prospered. Its activities have been considerably broadened since January 1. The present administration opened its régime auspiciously by improved financing of its standards committee work by obtaining from the National Automobile Chamber of Commerce, Inc., a substantial donation, which has enabled the society to pay railway mileage to the members of its standards committee attending quarterly standards meetings in New York. The result is a greatly increased attendance at these meetings and higher efficiency from those attending. This was the first year in which these standards meetings have been conducted quarterly, and the progress made in arriving at new standards, eliminating others that have proved useless, or writing specifications of metals off the data book, indicates the broad grasp of the problem by the present administration.

Approximately one-third of the specifications of steel have been removed from the data book. The work of adding new standards has gone perhaps more slowly than formerly, the standards committee as well as the various sub-standard committees preferring to make progress very slowly to that less conservative policy of doing only to undo a year or so hence.

Besides the iron and steel specifications the society's standards committee has made important strides toward the standardization of many of the parts for commercial and passenger vehicles. Twelve new standards have been adopted during the year. The introduction of the Cleveland section to the society is also a step in advance, as it is through the monthly section meetings in various cities that the work of the society is materially advanced.

Eight-Cylinder Cars

THE year of 1914 has been one prolific in engineering upheaval, and whether some of the developments that have taken place in the industry can be designated as progress only the passage of years will determine. The eight-cylinder motor has made its début, has been adopted by two makers and gives promise of adoption by several more before 1915 is many months old, widespread activities pointing in this direction havng been well known for several weeks. The eight-cylinder is not new; France has built it in a limited quantity for many years; it has been sold in considerable numbers in America, and against its success nothing can be said; but the American maker is catering to a fastidious buying clientèle, and it will only be after the eight has been tried against the six and the four that the final trend can be deciphered. The return to the smaller four is a characteristic, not spectacular but yet present.

Many other engineering movements have taken shape during the year, the cord tire, new systems of gasoline feed, etc., but these are reserved for the engineering review of the year to appear in THE AUTOMOBILE for December 31.

Factory Financing Conservative

THE year has not been spectacular with big financing schemes, with the gathering together of many small units or factories into large organizations, such as was the order a few years ago; rather factory financing has been comparatively conservative, money not being over abundant for manufacturing enterprises. Yet the year has not been dormant, no fewer than twelve out of sixty-six of our leading automobile companies having increased their capital during the year to the extent of $8,762,000, or an average of $13,275.75 per concern. With some this new capital has been needed to take care of building operations; with others it has been required for expansion and increased production.

In the truck field, four out of twenty-nine companies increased their capital over $2,800,000.

In the accessory field this program of enlargement has been carried on and, although it is impossible to give reliable figures, our compilations show, of about 150 leading makers, fourteen have increased capital to the grand total of $2,318,000.

Substantially Increased Profits

A RÉSUMÉ of annual statements published during the year discloses in general favorable financial conditions, nearly all of our concerns showing substantially increased profits. The Ford statement showing its accumulated profits of $48,000,000 is abnormal and is far in advance of the general condition. It should not be accepted as even indicating the average condition. On the other hand, the General Motors issued a most creditable statement, revealing profits of $7,947,413; the Willys-Overland statement was particularly good, with profits of $5,864,858, as compared with $5,705,537 for the previous year. The Packard statement showed a surplus of $1,797,820.42 for the year; Goodyear handed down a report showing $3,091,165 over previous years, and a general résumé brings to the surface many very favorable financial records.

Nineteen hundred and fourteen can be recorded as a year approaching the average in the amount of factory building activity embracing the occupancy of new factories and the erection of additions. Several new factories have been occupied, these including Gray & Davis, Paige-Detroit, New Departure, Stutz, Ever-Ready and others. Those included in the list of additions to present facilities are Overland, Reo, Hudson, Kissel, Stutz, Vulcan, Hupp, Dodge Bros. Among the truck concerns making additions are: Lippard-Stewart, Kelly-Springfield, Four-Wheel Drive, Nelson & LeMoon and Motokart.

Very general activity in increasing factory facilities marks the accessory industries, such increases being too numerous to mention here. They are to be found elsewhere in this issue.

A brief enumeration of what some of these individual concerns have done and the money expended will serve as a conservative criterion of building progress, the detailed program of the different concerns appearing on other pages of this issue, where many of the new factories or additions are illustrated.

Increased Car Production

WITH increased factory facilities we look to increased production, and it would be disappointing if we did not meet with many evidences of increased production for the year as compared with 1913. Briefly analyzing state registration figures for the year substantial increases are found. Total registrations for the country up to October 1 are 1,735,369 as compared with 1,253,875 for the 12 months of 1913, this showing a gain of 481,494, not taking into consideration the last 3 months of the present year. The 1914 registrations for the twelve leading states up to October of the present year all exceed the total registration for the 12 months of last year. For New York State the total on December 17 was 155,000, as compared with a total of 122,411 for all of 1913, this allowing for duplicate registrations. Some of the increases in other states for 9 months this year against all of last year are: Pennsylvania, 46,595; Ohio, 32,896; Illinois, 32,025; Iowa, 29,889; Texas (estimated), 20,638; California, 58,061 (partly due to new registration law); Michigan, 20,411; Indiana, 21,962; Nebraska, 14,955; Missouri, 12,472, and Massachusetts, 12,140.

Profit-Sharing Shows Results

FROM a financing viewpoint, Henry Ford's co-operative profit-sharing plan with his employees announced in January immediately became a matter of international interest, and since then the announcement of the price reduction of $60 per car and of his additional plan to rebate $40 to $60 to every buyer of a Ford car upon the condition that 300,000 are sold in the period from August 1, 1914, to August 1, 1915, has done much to demonstrate the magnitude of the organization and the efficiency with which it is conducted. The announcement of a surplus of $48,827,032.07 in the annual statement, with $27,441,468.79 cash in the banks, have substantiated previous convictions.

Up to the present approximately 87 per cent. of the employees have qualified as eligible to participate in the profit-sharing plans, and an analysis of the factory force shows that Ford's plan was based on broad ethical plans, foundation stones mutually profitable to employer and employees. The movement must be considered a revolutionizing one in the industrial field.

War Affects Export Business

THE year 1914 opened auspiciously for automobile exports, but unfortunately this desirable program was cut short by the war. Not only was our foreign business increasing with Europe, particularly in the low-priced car field, but statistics from Australia showed that the United States exported the most automobiles to the Antipodes, but that the total value of British car exports exceeded those from America by $455,100, amounting to $1,491,525, while the American cars were valued at $1,036,425. Comparing this year with previous years, America's trade with Australia has been developing very rapidly.

Our South American business has not shown the improvement that was anticipated, partly due to the handicap our makers are under in not having American banks with branches in the leading South American cities. Fortunately one of our leading banks has already opened a branch in Rio de Janeiro and expects to have another branch opened in Buenos Aires before many weeks, so that this enterprise, together with the credit reports already being compiled, should greatly facilitate our business in many of these Latin-American countries. The most of South America has been under a moratorium since the opening of the war, and naturally business opportunities are not the most inviting, particularly as Europe was the banker for South America. Now with this banker engrossed in war the new program is that of our having to develop sales in a land not naturally favorably disposed to us and of having to finance the deals as well. No mean program, and one that calls for the best genius of our industry. But in spite of depression, not a few of our car and accessory concerns have dispatched special trade emissaries to these Latin-American countries with the grim determination of building up a trade along the same lines as the European experts in export fields have done, namely, locating in these lands, studying the characteristics of the people, analyzing the business methods, and preparing plans accordingly.

Passing of the Cyclecar

INDUSTRIALLY the wane of the cyclecar movement, in fact, you might almost say the elimination of the movement for the present at least, must take its place as one of the industrial cycles. The opening weeks of the year saw a perfect tidal wave of cyclecar enthusiasm. Concerns were being incorporated nearly every day, a national organization was formed of the manufacturers, a national sport-governing organization was launched, but today little is heard of the typical cyclecar. A score, perhaps two score, of the concerns have discontinued, and now the movement is to the conventional miniature car, a vehicle with a four-cylinder motor, a two or three-speed gearset, shaft drive, steering and general running gear details in conformity with standard practice. This trend of the cyclecar movement is a page from the history of the industry in England, where the cyclecar was conceived.

Why the sudden eclipse in America is difficult to answer, many factories combining. There was much stock-jobbing indulged in, selling stock on vehicles that were on paper but which had never reached the practical stages. There were many cyclecars launched without being backed up by sufficient engineering talent, and these had to go the certain path of the weak. There were many concerns not sufficiently backed financially to carry on production. But the public was not ready for the cyclecar. Tandem seating was an innovation; the narrow tread was not liked; you sat too much in the dust zone and too near the poles of horse wagons. There unquestionably will be a revival of the movement, perhaps more along the miniature car lines, with standard treads, until such times as our highways over all the states resemble our city boulevards.

A Good Contest Year

THE year has been an active one in contests, the official report of the American Automobile Assn., the official sport-governing body of the automobile industry, showing a total of 120 sanctions issued for the year, as against 101 in 1913, 132 in 1912, 117 in 1911 and 166 in 1910. Speedway and road racing enjoyed the major share of the sporting season, hill-climbs and reliability or endurance contests having a very scant following. The last few months have been considerably enlivened by the many certified trials held by different makers and conducted under official sanction by accredited technical representatives. These trials can only be interpreted as a striving for more accurate engineering information, and whether their mission is to determine fuel economy, tire efficiency, low-gear ability, etc., there is but one comment, namely, that they have stimulated critical interest in their line and should be emulated by many other makers.

The Tire Industry

THE tire industry has had a relatively peaceful existence since January 1 and the new year will witness approximately the same tire prices as ruled a year ago. The war caused a brief flurry, the price of crude bounding in a few days from 55 cents per pound to $1.10. There was an upshot in prices and something in the nature of a stampede among dealers to move the goods on hand. Owners bought very generally, and big stocks were moved, the feeling being that the importation of plantation rubber from the East Indies through London might be endangered by the war, particularly if Great Britain, who handled the rubber situation, should not maintain strict control of the high seas. Within a few weeks after the declaration of war the situation cleared and crude fell to normal, but the last month has brought renewed anxiety, due to the embargo placed on crude by Great Britain. It is not known when this embargo will be lifted and whether it was enforced due to the feeling that much of the crude brought from the east in British bottoms was eventually reaching her enemies, or whether the possibilities of interruption in the Suez Canal trade because of the Turkish hostilities was the dominating factor. As it is, the embargo remains and crude is about 80 cents per pound, with little hope of much East Indian production arriving in the immediate future.

Crude from the East Indies plays a very material part in the tire industry, in spite of the much-heralded Para gum from South America. The quantity of Para gum used in our tires is small as compared with that of plantation rubber from the East.

1914—A Good Contest Year

High-Speed, Small Bore Motors the Engineering Feature in Racing—102 Sanctions Granted—Speedways Popular—Many Individual Tests of Stock Cars for Speed and Economy

CONTESTS in 1914 attracted slightly more attention than a year ago, although few additional factories lent their support. Not more than one large concern, Maxwell, entered the field with specially-built racing machines and a comprehensive corps of drivers. Speedway races showed increased popularity, Indianapolis, Sioux City, Ia., and Tacoma, Wash., staging very satisfactory meets. Road racing was scarcely up to the mark of 1913, Elgin, Santa Monica, Corona and the desert duel between Los Angeles and Phoenix, being the major events. A very perceptible improvement took place in events on circular mile horse tracks. A series of 100-mile races with purses of $1,000 for winning, with good second and third money, drew the best racing talent and proved very popular.

Many Certified Trials

A most satisfactory development in contests during the year was the certified trials movement, in which individual car and accessory organizations took out sanctions and had trials made on fuel consumption, for low-gear traveling, for speed for 1 hour or longer, etc. These certified trials created a great deal of interest, and did much to stimulate sentiment.

More makers than ever before availed themselves of the Indianapolis speedway for private speed and other tests and concerns which have long been out of racing held several official speed tests.

The hill-climb movement was at the lowest ebb for several years, only two climbs of importance being staged, one at Atlanta, Ga., and the other at Uniontown, Pa. Wisconsin had the only large reliability contest and there were fewer sociability and short outing trips than formerly. The inter-club contests promoted for years in Chicago were continued with old-time success. Only one large competitive fuel economy test was held, it being conducted in Harrisburg, Pa.

Small High-Speed Motors

From racing results the dominating conclusion was the great performance of the small, high-speed motors, cars of 300 cubic inches or under showing higher maintained speeds than large 450- or 600-cubic-inch motors of previous years. The years of work that Europe has been expending in the development of the small high-speed, high-efficiency motor were well demonstrated at Indianapolis' 500-mile race, where an especially small car finished second. It can be accepted that 1914 definitely proved the fallacy of the large motor and heavy chassis for long-distance speedway or road races. The small motors with four valves per cylinder gave a wonderful account of themselves, both in America and abroad. More valve-in-the-head motors were used than ever before, though while these won the majority of races, the records of the year were established at Corona with a Mercer T-head design.

Cord tires came before the public more than ever before, and contests of 1914 proved as conclusively as previous years that car weight, car balance, and the resulting tire wear are still the controlling factors in racing.

Few Stock Car Contests

Unfortunately practically all contests were for non-stock cars, and it was exceedingly interesting when at certain times certified speed trials of stock cars demonstrated that we have stock cars that can maintain high speeds for 1 hour or longer, and that the public would still be greatly interested in more stock car performances.

In 1914 the Contest Board of the American Automobile Assn. issued 120 sanctions as compared with 101 last year, 132 in 1912, 117 in 1911 and 166 in 1910. A further analysis of the 120 sanctions issued in 1914 shows that fifty-two were on 1-2-mile dirt tracks, thirty-six on 1-mile dirt tracks, ten were road races, eight reliability tests, two hill-climbs, four certified trials, and one each of beach races, commercial vehicle tests. The Indianapolis, Tacoma and Sioux City speedways were the only ones to receive sanctions during the year.

This segregation indicates a falling off in the number of road races, which is explained by the fact that 1914 saw few class races, there being really only six events of major calibre, the Grand Prix and Vanderbilt at Santa Monica, the Chicago Automobile Club cup and the Elgin National trophy at Elgin, Ill., the Los Angeles-Phoenix desert race and the Corona races. In 1913 San Diego had three road races, Corona had two and Tacoma had three. This year San Diego was not in the running, Corona had only one, and Tacoma was put into the speedway category. Both the Los Angeles-Sacramento and Albuquerque-to-Santa Fé road races were abandoned this year.

Although road races in 1914 were fewer than ever before, yet the number of starters was 105 per cent. greater than in 1913 and the largest since 1911. There were 170 starting in the ten races whereas, in 1911, 202 started in twenty-seven events.

An Increase in Speed

This year showed an increase in speed. In each of the five classics the previous record for that particular race was beaten: De Palma's record of 75.49 m.p.h. for the Vanderbilt beat Mulford's mark of 74.07 at Savannah; Pullen raised Bruce-Brown's mark of 74.45 for the Grand Prix at Savannah to 77.2 at Santa Monica; De Palma raised the Elgin course mark from 66.8 to 73.9 and the Elgin National, formerly held by Gil Anderson at 71.5, to 73.53 and Pullen raised his old mark of 75.03 at Corona to 87.7.

This year saw about the same number of makers supporting racing teams, there being forty-seven makes represented as against forty-six in 1913, forty-four in 1912, forty-four in 1911, fifty-five in 1910 and sixty-three in 1909.

New speedway records were made at Indianapolis in the 500-mile race. These ranged from 20 miles up to 500. Oldfield in the Stutz gets the 20 and 25-mile marks and all the others go to the foreign cars. Speedway racing seems to have come into its own, for this year there were five races in this category, each won by a different driver and car. The Indianapolis 500-mile race was won by René Thomas in a Delage; Sioux City's 300-mile event went to Rickenbacher in a Duesenberg, and at Tacoma, the winners were Cooper, in a Stutz; Hughes in a Maxwell, and Parsons in a Frantz.

The year of 1910 was the next largest for speedway events, there being then three speedways in operation, Indianapolis, Atlanta and Los Angeles. In 1915, Indianapolis, Sioux City and Tacoma, it now appears, will be augmented by big tracks at Minneapolis, New York City, Omaha, and Chicago.

Races Longer Than Before

Referring back to road racing it is shown that another tendency noted this year was to make the races longer and the ten road races totaled to within 130 miles of the distance covered in the sixteen races in 1913. This gives 1914 the record average mileage with 354 miles as against 207 in 1913, 243 in 1912, 206 in 1911, 211 in 1910 and 211 in 1909.

The average time of all the finishers, too, was better, the figures giving 54.91 miles per hour, as against 54.68 in 1913, 54.49 in 1912, 59.51 in 1911, 51.58 in 1910 and 50.62 in 1909.

The average time of each winner was slower than those of 1911 and 1912 and faster than 1913. The following gives the average time made each year: 1914, 58.69; 1913, 57.7; 1912, 60.25; 1911, 63.22; 1910, 53.8 and 1909, 49.2.

Racing on 1-mile circular dirt tracks was more popular this year. A series of 100-mile races with keen competition between such drivers as Burman, Mulford, De Palma, Tetzlaff and Alley, brought large attendances. It is remarkable that in each of these races the 100-mile dirt track record was broken. First De Palma broke it at Brighton Beach, by making it in 1:40:15, then Burman at Kalamazoo, lowered that mark to 1:34:29 to 1:32:54 at Galesburg, and to 1:31:30 by Alley in a Duesenberg at Hamline.

S. A. E. Advances Along Three Broad Lines

Standardization, Research and Social Activities Advanced—Over Sixty Papers Read—Twelve Sets of Standards Adopted—Cleveland Section Added

WHEN President H. M. Leland of the Society of Automobile Engineers spoke at the last Summer session of making two blades of grass grow where but one grew before, he struck the keynote of progress for the society. The organization has three broad lines of endeavor which may be laid down as the promotion of standardization in manufacture, research and the promotion of good fellowship and acquaintance among the men who make up the automobile industry. Along all these three lines Mr. Leland can truthfully state that the close of his administration sees many more blades of grass than the beginning. Progress has been made.

Twelve New Standards

In standards work, the addition of twelve new sets of adopted specifications and the modification and simplification of several others are milestones along the march of the committees in charge of this work towards the goal of maximum efficiency and economy in the manufacture of automobiles. The adoption of S. A. E. standards by other recognized engineering bodies is another important step. The Electric Vehicle Assn. has adopted the standards of the society as regards the electric vehicle in toto. The American Society for Testing Materials is considering the adoption of the entire list of S. A. E. steels. The recognition and confidence of other engineering bodies is a big factor in the success and growth of the society.

Over Sixty Papers

The fruits of research are the papers which are brought before the society for discussion and which then enter the transactions as a part of the permanent records. These papers not only represent private research but are also the reports of committees which have been definitely assigned to the work. In this committee investigation work the sections of the society have been a great factor and the work of committees on such subjects as gasoline-electrics, kerosene carbureters, etc., is bearing fruit in the shape of valuable data for use as reference in future developments. During the year more than thirty papers have been presented before the sections for discussion and at the two semi-annual conventions there were thirty-one others, fourteen in January and seventeen in June. Thus a total of more than sixty papers on selected subjects and the discussions which resulted from these have become part of the records of the society during 1914.

Cleveland Section Added

On the promotion of acquaintanceship it is impossible to set an accurate gauge. The social end of the society's work is aided to an immeasurable extent by the monthly gatherings of the four sections in New York, Detroit, Indianapolis and Cleveland. The last named section is another of the steps forward during the year as it has come into existence but recently. Probably the biggest opportunities for the formation of friendships are the semi-annual conventions. This year, as in the past, the winter session was held in January in New York City. The summer session was held on the sands of Cape May, N. J.

A step forward in the work of the standards committee has been made in the practice of holding a standards committee convention previous to that of the regular semi-annual conventions. This affords the members of the committee a chance to organize their work and establishes a firm stepping stone on which to base their reports to the society as a whole. In order to promote the best possible attendance at these important meetings the mileage of the members of the committee is now paid by the society. At the last convention of the standards committee held in October, seventy-five members registered during the progress of the meeting which occupied 3 days.

During this time the reports of twelve divisions which are actively engaged in the formulation of standards were heard. This offered the opportunity of telling the manner in which the specialized work was being conducted and enabled the committee as a whole to offer suggestions and discuss the manner in which the reports will be made to the entire society at the January 1915 session.

Fewer S. A. E. Steels

At the meeting in January 1914 eight new standards were adopted. At the summer session there were four others, making twelve new sets of standards for the year. These covered broaches, truck tire sizes, insulation tests, storage battery dimensions, battery rating, air pump dimensions, spark plugs, cotter pins for yoke ends and sets of specifications for S. A. E. alloy and carbon steels. In the iron and steel standards the adopted reports were in the line of simplifications of existing standards through the elimination from the list of steels, several that were not used to a sufficient extent to justify their retention.

Twenty-nine subjects are now engaging the attention of the society in regard to their standardization. These are noted in the accompanying table.

Many of these subjects are so broad that they are naturally subdivided and have certain portions of the work in the hands of sub-committees.

In the internal management of the society there have been several important milestones passed. The adoption of a new constitution which incorporates many features which broaden the work is one of the most important. The question of student enrollment is of great importance in the work of the society in developing men for the automobile industry. At the June meeting it was suggested that a paragraph be added to the constitution of the society putting it within the power of the council to enroll bona-fide students of automobile engineering under 30 years of age and for the sum of $3 annually allow them to receive the Monthly Bulletin of the society. To enter as a student, the endorsement of a member of the society and the approval of the council is necessary. Three student enrollments were approved during November.

Nine Tire Sizes

There are many steps in the standards work, which, although not adopted by the society this year, really belong to the year's work. One of the most important of these, both to the manufacturer and the user of cars, is the standardization of pneumatic tire sizes. There are now fifty sizes manufactured. If the proposed standard becomes a part of the policy of the tire makers there will be but nine, exclusive of the oversizes. The tire makers are heartily endorsing this stand because it will not only be a source of economy to themselves but will also work a benefit to the dealer, who will be able to keep himself stocked more readily and to the user because he will have less difficulty in securing the size tire he wants.

The sizes of tires which the division in charge of this work recommends for adoption as standard are the 30 by 3; 30 by 3 1-2; 32 by 3 1-2; 32 by 4; 34 by 4; 34 by 4 1-2; 36 by 4 1-2; 38 by 5 1-2, and 36 by 5. The feasibility of reducing the fify odd sizes of tires to the above nine will be realized when it is understood that 85 per cent. of the tires on cars now in use are among the sizes mentioned. The society expects that tire makers will manufacture oversizes for these tires but that the makers of cars will adopt one of these standard sizes, allowing the user to fit the oversize should he deem it necessary, owing to the carrying of more than the weight for which the cars are designed or for roads of more than ordinary capacity for tire wear.

Cars Undertired

The question of tire equipment has been dealt with more extensively this year than any other. It is stated in the reports of those who have investigated conditions for the pleasure car wheels division that more than 90 per cent. of our cars leave the factories with a greater load on the tires than the average prescribed by the tire making concerns. For this reason a special committee is considering the economics of using larger tires with less inflation. While this matter will fall into next year, its initiation is one of the features of accomplishment during the 1914 season.

Many of the fittings under the jurisdiction of the miscellaneous division are of importance. A new spark plug, not to replace, but to supplement the present S. A. E. standard plug is suggested. This will take a larger porcelain than the old standard plug and the dimensions will be such that it can be screwed into place by hand, the final tightening only being made with a wrench.

A work of great importance to the society is the maintenance of the data sheets which are issued in loose leaf form. Under chairman B. D. Gray of the data sheet division the work of keeping these sheets up to date has taken on a new life. The result has been the entire revamping of the data sheets. They now keep pace with the work of the standards committee and as a result are to be found on the desks of draughtsmen and engineers as instruments of active use. The standards so far adopted are printed on these sheets together with a large amount of valuable data in the shape of tables and engineering facts and formulæ.

A new division of the standards committee which will doubtless prove of value in keeping the S. A. E. in touch with the outside world is the standard exchange division. The function of this body is to keep abreast of the standards and engineering practices adopted by the society and by written communications and conferences arrange that the established standards of other organizations harmonize with those of the S. A. E. insofar as it is practicable. In addition to the E. V. A. and the American Society for Testing Materials the division is working in conjunction with the Automobile Engine Manufacturers Assn. A definite aim in conjunction with the work of this organization is the adoption of a standardized set of dimensions for bell housings for unit power plants. This would lessen to a large extent the troubles of the parts manufacturers in designing clutch housings and gearboxes and would tend towards reducing the prices on these units.

Throughout the year a question which has been a source of considerable debate in the society and which now seems to be solving itself is that of the single vs. two-wire scheme in installing electric lighting and starting outfits. At the summer session of the society the standards committee brought to the society as a whole the resolution that the single-wire system be adopted as recommended practice. A warm debate ensued on this in which it was brought out that many of the members did not think that the single-wire system was safe. The objection urged against it was the risk of fire and the complications necessitated by the installation of fuses. No decision could be reached. Since that time the division to which the matter was referred back states that of the 1915 cars 220,000 will be equipped with single wiring and 98,000 with double wiring. It is felt that in view of the remarkable trend towards the single wire system a recommendation by the society would be superfluous. The information upon which the facts are based comes from a declaration of the intentions of thirty-eight makers. Twenty-seven of these favored the single wire and eleven the double wire.

Owing to the agitation against glaring headlights which was inaugurated early in 1914 in many of the largest municipalities, resulting in legislation which had different requirements for lights in different cities, it was thought that the matter should be investigated by the standards committee of the society. In this connection a sub-committee was appointed by the electric equipment division. It will be the work of this committee to determine a standard method of measuring the quantity of glare in order that some basis will be had upon which to base a uniform legislation. This work is well under way and must be included in any review of the progress of the year.

Standards Are Used

All the work of the standards committee as reviewed in these pages is the product of work which stands out owing to its timely importance. In addition to this, however, there is a large amount of technical data which has been evolved as the result of patient and painstaking effort on the part of the committee in gathering data from the makers.

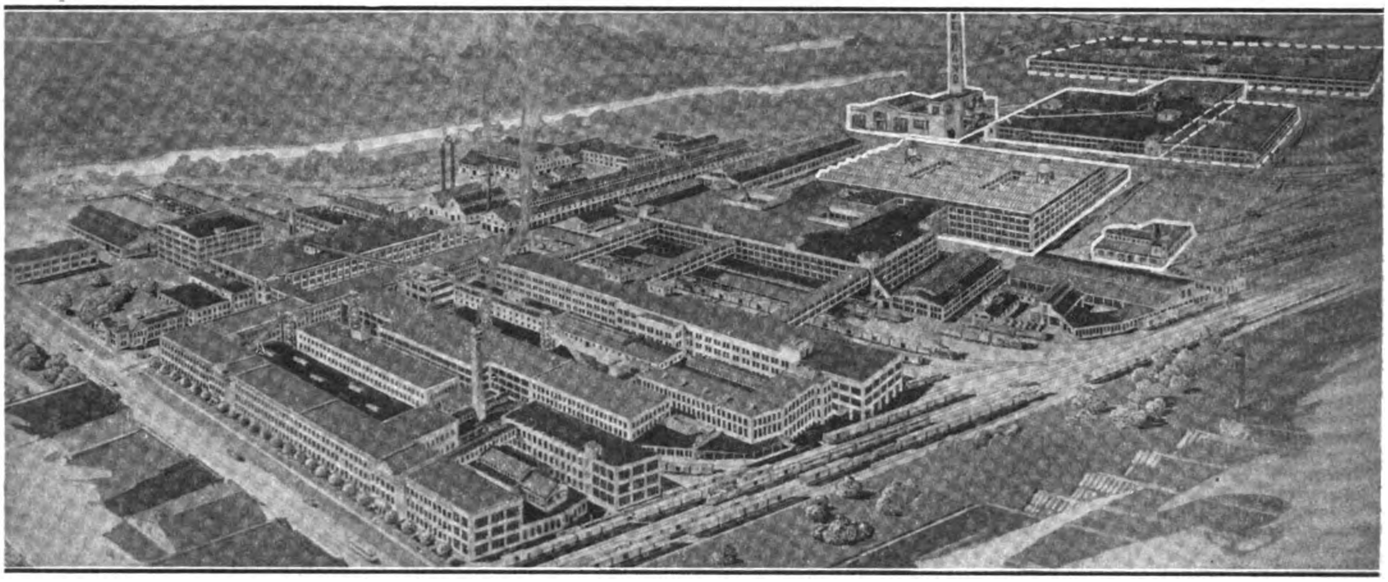
The proof of the pie is in the eating and in the standards work the eating of the pie is paralleled by the using of the standards in the actual work of designing the cars. The year of 1914 can truthfully be said to have seen a considerable advance in this respect. Car manufacturers who are turning out products which are to a large extent assembled are learning to specify S. A. E. standards foı their parts. The axle and gearbox manufacturers bring ample testimony as to this and none are more active participants in the actual work of the standards committee as well as in the discussions on the standards than are these makers. The contributions of the tire makers towards the adoption of a series of standard tests on demountable rims is one of the bright spots in the technical history of the standards committee work, showing that manufacturers whose industries are affected by the standards investigations are willing to lend time, men and money to the efforts to produce standards that will cut manufacturing costs.

It is to be regretted that the European war cut short the negotiations for the foreign visit this year. Many had expressed their intention of participating.

Subjects Now Engaging Attention of S. A. E. Standards Committee

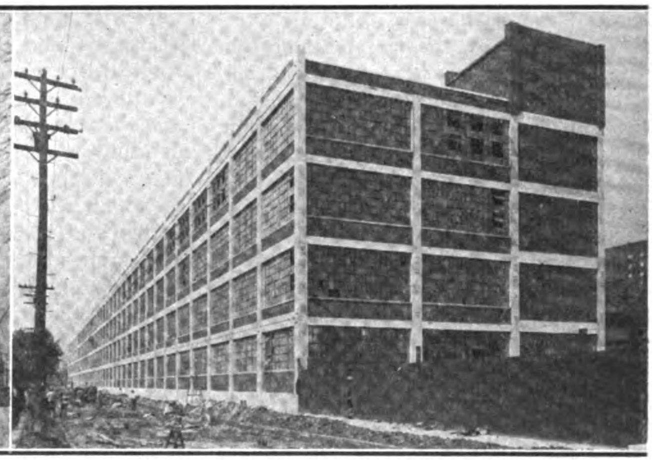
1—Truck wheel felloe bands
2—Truck wheel tire clamps
3—Anti-glare devices
4—Single wire fittings
5—Lamp nomenclature
6—Lamp fittings
7—Lamp bracket dimensions
8—Junction boxes
9—Frame sections
10—Lock washer material
11—Vertical carbureter flanges
12—Carbureter fittings
13—Air pump dimensions
14—Yoke end pins
15—Hex spark plug shell
16—Cotter pin sizes
17—Physical properties S. A. E. steels
18—Steel casting specifications
19—Pneumatic tire sizes
20—Tire inflation pressures
21—Demountable rims
22—Roller bearing sizes
23—Thrust bearing sizes
24—Tap drill sizes
25—Vehicle horsepower formula
26—Electric motor voltages
27—Electric vehicle ratings
28—Battery appliances
29—Industrial trucks

Some Building Activities During 1914—

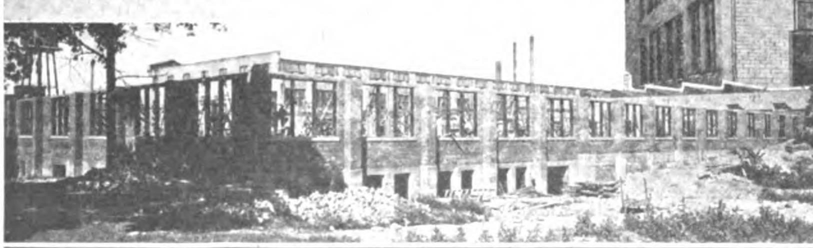


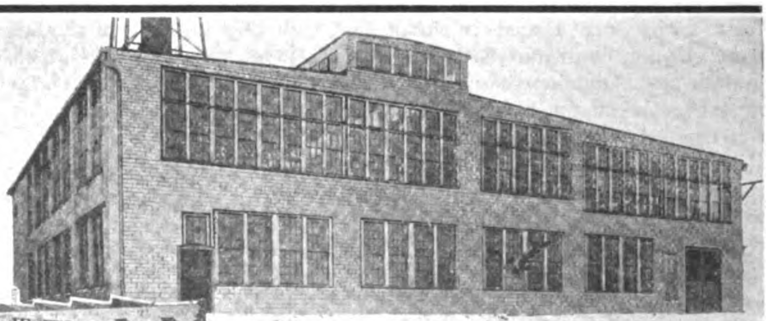
Bird's-eye view of Willys-Overland factory at Toledo, O., showing at right new buildings erected during the year at cost of $1,000,000. Completed structures are indicated by white lines surrounding the buildings. Other improvements under way are shown by dotted lines. The additions represent an increase in floor space of 1,985,000 square feet

New factory occupied by the Paige-Detroit Motor Car Co. in February of this year. New machinery to the value of $65,000 has been added for this new plant



Dodge Bros., Detroit, have increased their facilities during the year by a four-story assembly building, 876 by 70 feet, which, in addition to the other plants, gives a total area of 18.75 acres



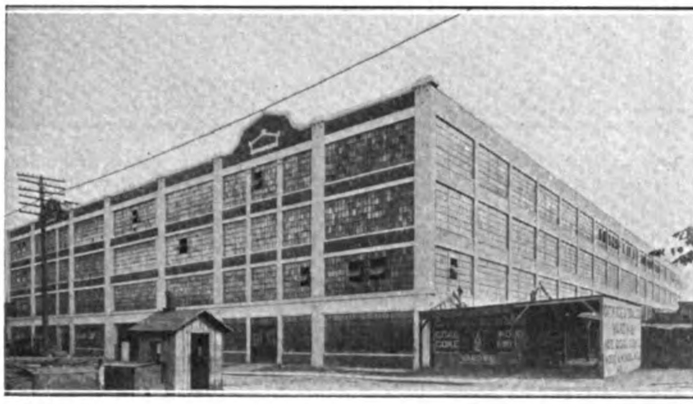


The Reo Motor Car Co., Lansing, Mich., has added 196,000 square feet. One of the new buildings (lower left) is a three-story one for various assembly departments and another is for heat-treating work. Cost of the additions was $110,000

The Hudson Motor Car Co., Detroit, has increased its floor area by adding a third story to the main building (upper left) and also to three of the wings, the additions being shown in dark in the illustration

The Kissel Motor Car Co., Hartford, Wis., has added 60,000 square feet for foundry and body-building work (upper right) at a cost of $60,000

Car, Truck and Accessory Plants Expand



The Cole Motor Car Co., Indianapolis, Ind., early in the year completed its new four-story factory measuring 400 by 100 feet, this new building incorporating the executive offices of the company

The Stutz Motor Car Co., Indianapolis, Ind., has occupied an entirely new factory building which increases its floor area 60,000 square feet at a cost of $100,000

THAT business conditions are really not as bad as some people would have us believe is the only conclusion possible after a close survey of the automobile, motor truck and accessory industries, particularly in regard to the progress in increasing manufacturing facilities.

In spite of the alleged general depression, out of seventy of our leading car makers, twenty-two added to their factory area, while twenty-three increased their machinery and other equipment. The total floorspace added is over 1,125,000 square feet, the expense incurred amounting to over $1,526,000. Machinery purchased represented an even greater expense totaling $1,720,000.

Among thirty of the leading truck makers, seven added to their floorspace, the increase amounting to 307,320 square feet at a cost of $72,000 and twelve bought new machinery and equipment, the total outlay being $156,200. Two entirely new factories are reported.

Of the 150 accessory manufacturers who reported, forty-seven increased their space by a total of approximately 2,000,000 square feet at a cost of $2,900,000. Seventy-eight of them added to their machinery and equipment, the amount invested in this direction totaling $2,400,000. Eleven entirely new factories and one partially new one are reported.

What the Car Builders Have Done

The Auburn Automobile Co., Auburn, Ind., has expended $10,000 in new machinery.

Consolidation of the Allen Motor Car Co., Fostoria, O., with the Sommer Motor Co., Bucyrus, O., gave an added floorspace of 40,000 square feet while test and first assembly buildings added during the year gave 35,000 square feet. New machinery, $25,000. New buildings, $20,000.

The Buffalo Electric Vehicle Co., Buffalo, N. Y., occupies an entirely new factory, five floors in height and 155 by 100 feet.

Cadillac Motor Car Co., Detroit, has increased its factory by 100,000 square feet. New machinery and equipment, $600,000.

New machinery to the extent of $42,000 has been purchased by the Chandler Motor Car Co., Cleveland, O.

The Cole Motor Car, Indianapolis, Ind., has added a four-story factory building 100 by 400 feet, which is illustrated on this page. The new building incorporates the executive offices of the company.

The quarters of the Dile Motor Car Co., Reading, Pa., has been enlarged 4000 square feet by the occupation of the new two-floor factory 60 by 150 feet. New machinery, $5,000.

Dodge Bros., Detroit, Mich., increased facilities by a four-story assembly plant 876 by 70 feet. The total floorspace of the factory is now about 18¾ acres.

Dorris Motor Car Co., St. Louis, Mo., has spent $5,000 in new machine equipment.

Fargo Motor Car Co., Chicago, Ill., has occupied an entirely new factory, two stories in height and 200 by 50 feet. New machinery, $1,900.

Grant Motor Car Co., Findlay, O., is established in new quarters, giving it a floorspace of 75,000 square feet.

A third story is being added to the factory of the Hudson Motor Car Co., Detroit, increasing the space from 8 to almost 11 acres. The third story is being added to the main building and three of the wings, making a total length of 2,200 by 62 feet.

The Hupp Motor Car Co., Detroit, has added an office, a dynamo-

Bird's-eye view of the combined plants of the New Departure Mfg. Co. at Bristol and Hartford, Conn. The six-story building at the left is a new $250,000 structure occupied during the year and is one of the models in its line

New eight-story factory of the American Ever Ready Co., Long Island City, N. Y., 200 by 300 feet and representing an expenditure of $1,000,000

The Auto Parts Co.. Providence, R. I., by erecting a new assembly shop at a cost of $25,000 has added 12,000 square feet of floor space

meter building and a garage, 8,336 square feet, obtained at an expenditure of 6,600. New machinery, $53,188.

Two buildings, costing $35,000, have been added to the plant of the Kissel Motor Car Co., Hartford, Wis., giving an increase of 60,000 square feet for foundry and body building departments. About $60,000 worth of new machinery.

Krit Motor Car Co., Detroit, Mich., has remodeled and enlarged its enameling department at an outlay of $1,500. New machinery, $6,000.

New machinery worth $500 has been purchased by the Lenox Motor Car Co., Boston, Mass., during the past year.

The L. P. C. Motor Co., Racine, Wis., has added 108,000 square feet. New machinery, $60,000.

The Lyons Atlas Co., Indianapolis, Ind., has altered a great many buildings covering an area of several hundred thousand square feet at an expense of several thousand dollars.

McFarlan Motor Co., Connorsville, Ind., has remodeled its factory and added a body-building department increasing its floorspace 18,000 square feet at an expense of $10,000.

Additions to the plant of the Metz Co., Waltham, Mass., consist of assembling, enameling, grinding, foundry and wood working departments, giving an increase of 160,000 square feet at an outlay of $250,000. The new additions are 400 by 400 feet. New machinery, $275.

The Milburn Wagon Co., Toledo, O., has rearranged its factory to take care of the new electric car departments, having added new offices with a floor space of 10,000 square feet.

Four buildings have been added to the plant of the Willys-Overland Co., Toledo, O., giving an increase of 1,985,000 square feet at a cost of $1,000,000. The buildings are as follows: four stories and basement, 410 by 500 feet; two stories and basement, 400 by 200; two stories and basement, 1,000 by 200; two stories and basement, 200 by 200.

Land comprising a tract 160 by 500 feet has been purchased by the National Motor Vehicle Co., Indianapolis, Ind., for a plant site.

The new plant of the Paige-Detroit Motor Car Co., Detroit, Mich., gives the company additional floorspace of 95,000 square feet and additional quarters rented in November give 49,000 square feet for the service department. New machinery, $65,000.

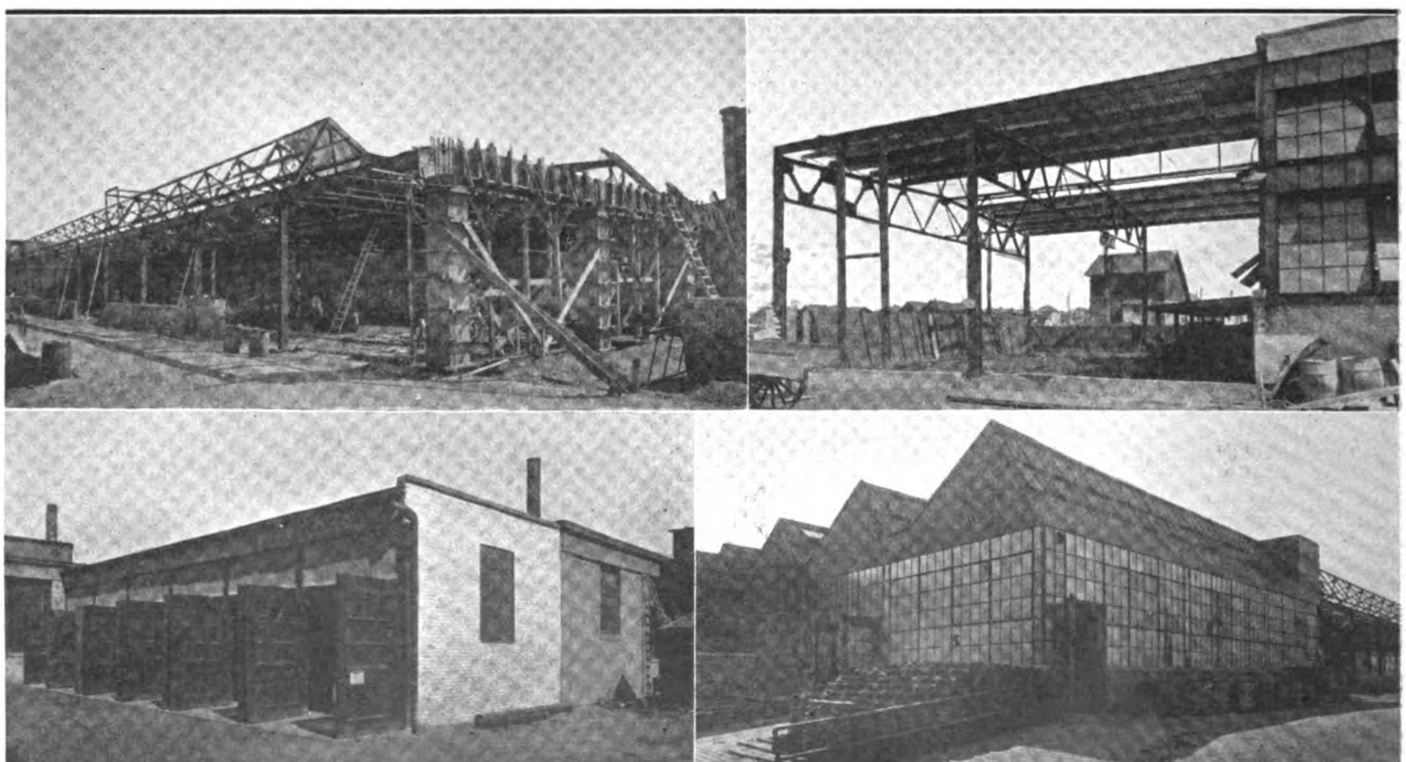
The Partin Mfg. Co., Chicago, Ill., purchased and occupied the factory formerly used by the Staver Automobile Co. in that city.

The Motor Car Mfg. Co., Indianapolis, Ind., has added 7,500 square feet.

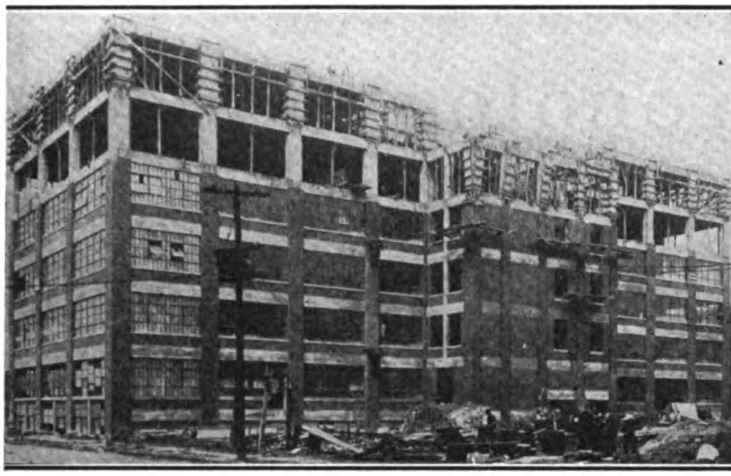
Machine tools to the extent of $42,000 and electrical and hoisting machinery worth $5,000 were added by the Pierce-Arrow Motor Car Co., Buffalo, New York, in 1914.

The Regal Motor Car Co., Detroit, Mich., invested $35,000 in new machinery and equipment.

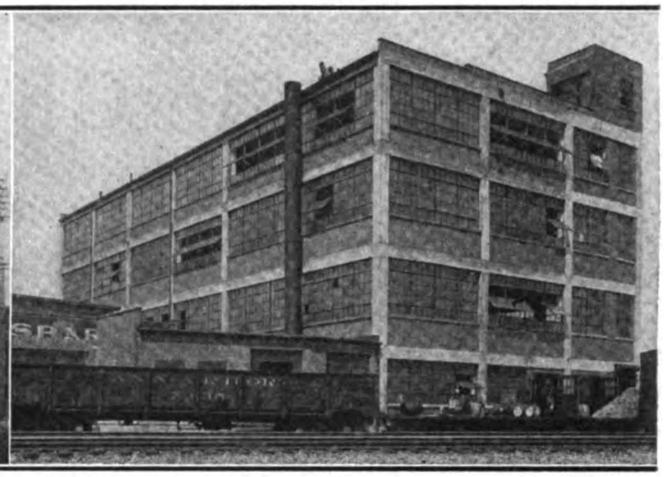
Reo Motor Car Co., Lansing, Mich., increased its floorspace 196,000 square feet. The additions represent an expenditure of $110,000, while machinery worth $240,000 and equipment worth $90,000 have been purchased. One of the three new buildings is a three-story structure to house the trim, top, gear paint and various assembly departments. A general machine shop 95 by 600 feet and another structure used for heat treating complete the list.



The Continental Motor Mfg. Co., Detroit, has added 75,000 square feet of factory area at a cost of $50,000 and has added new machinery to the value of $150,000. The additions include a machine shop, upper left in the illustration; addition to heat-treating department, upper right; a new garage, lower left, and a new steel stamping department, lower right



The Hyatt Roller Bearing Co., Newark, N. J., has added a six-story and basement structure, 200 by 75 feet and giving an increase in floorspace of 150,000 square feet



The Champion Spark Plug Co., Toledo, O., has completed a four-story addition giving an increase of 45,000 feet at a cost of $60,000. New machinery to the value of $100,000 has been added

The Saxon Motor Co., Detroit, Mich., has arranged to move into the factory formerly occupied by the Abbott Motor Car Co., which, with its 135,000 square feet of floorspace will increase the space of the company 85,000 feet.

The Sphinx Motor Car Co., York, Pa., purchased the four-story factory of the Hart-Kraft Motor Car Co., dimensions being 115 by 265 feet.

The Stutz Motor Car Co., Indianapolis, Ind., has added a new building, increasing its floor space 64,000 square feet at a cost of $100,000. The new structure is four stories, 80 by 204 feet, and will be used for assembly work. New machinery, $1,000.

New quarters are occupied by the Twombly Car Corp., New York City. The plant comprises six buildings, the largest of which is 450 by 100 feet. New machinery, $12,000.

An entirely new factory has been occupied by the Trumbull Motor Car Co., Bridgeport, Conn., giving the company 32,000 square feet of floorspace.

The Vulcan Car Co., Painesville, O., has added a final assembly room of 35,000 square feet at a cost of $10,000.

The Walker Vehicle Co., Chicago, Ill., has spent $10,000 on new machinery.

New machinery worth $2,000 has been added by the Waverley Co., Indianapolis, Ind.

The Woods Motor Vehicle Co., Chicago, expended $25,000 on new machinery.

In the Truck Field

The Atterbury Motor Car Co., Buffalo, N. Y., spent $2,000 for new machinery.

New machinery worth $3,000 has been added by the Blair Mfg. Co., Newark, O.

The Bowling Green Motor Truck Co., Bowling Green, O., expended $1,500 on new machinery.

The Couple-Gear Freight-Wheel Co., Grand Rapids, Mich., has bought $1,000 worth of new machinery.

The factory occupied by the new Denby Motor Truck Co., Detroit, Mich., has 20,000 square feet of floorspace.

New machinery worth $5,000 has been added to the equipment of the Duplex Motor Car Co., Charlotte, Mich.

Factory additions totaling 6,320 square feet and respectively 40 by 40 and 59 by 80, have been made by the Four-Wheel-Drive Auto Co., Clintonville, Wis., at a cost of $15,000. The additions will be used for power and painting departments. New machinery worth $25,000 has been added.

At the close of 1913 the General Vehicle Co., Inc., Long Island City, N. Y., moved into its new six-story main building. Machinery, $50,000.

The Kelly-Springfield Motor Truck Co., Springfield, O., has added two buildings, with a floor space of 26,000 square feet at a cost of $25,000. The additions are used for assembling and machine shop work. Machinery, $10,000.

The Knox Motors Co., Springfield, Mass., has purchased $3,000 worth of new machinery.

One addition has been made by the H. J. Koehler S. G. Co., Newark, N. J., at an expenditure of $20,000. It gives 4000 feet of floorspace for increasing production. Machinery, $30,000.

The Lippard-Stewart Motor Car Co., Buffalo, N. Y., occupied an entirely new factory with a floorspace of 50,000 square feet.

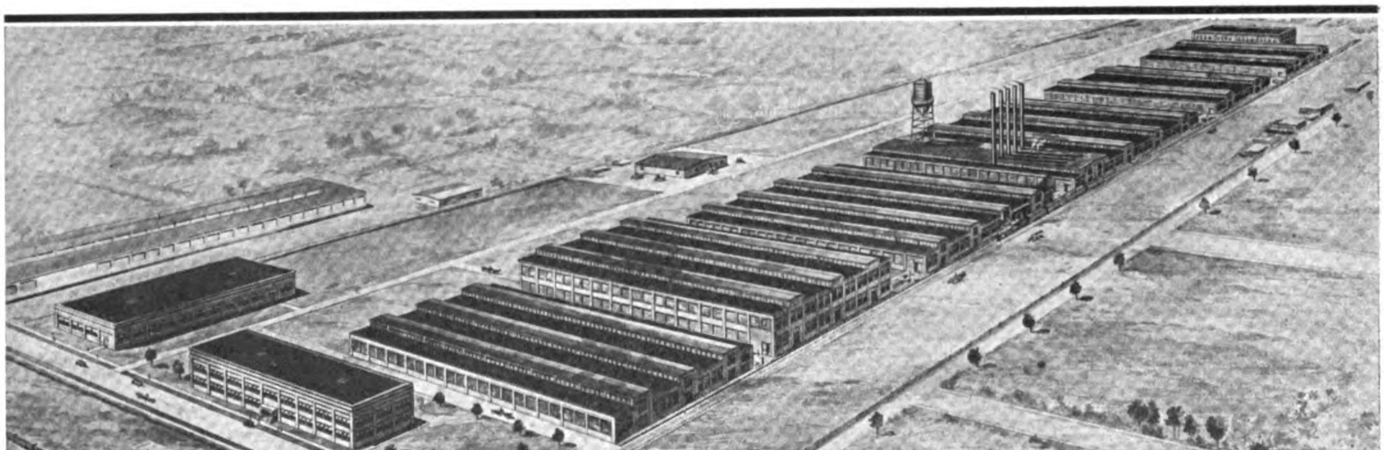
The MotoKart Co., New York City, is now erecting a plant at Scranton, Pa., which when completed will have a floor area of 195,000 square feet, comprising three manufacturing buildings, two 60 by 300 and one 60 by 250, a power building 50 by 100 and an administration building 50 by 250. Buildings will be two stories.

A one story building, 50 by 120, 6,000 square feet has been added by Nelson & Le Moon, Chicago, Ill., at an expenditure of $12,000.

Among the Accessory Makers

With the consolidation of the Splitdorf Electrical Co., Newark, N. J., and the Apple Electric Co., Dayton, O., the Apple company arranged for the removal of its plants to Newark by the purchase of buildings giving 70,000 square feet of floorspace, 5 acres of land and an office building.

(*Continued on page* 1174)



Bird's-eye view of the new plant of the Willard Storage Battery Co., Cleveland, O., which, when completed, will comprise ten buildings and contain 6 acres of floor space

Automobile Chronology for 1914

Engineering

January

1—145 American automobile manufacturers market 1914 cars at average price of $2,508.

2—American Voiturette Co. takes over manufacture of Keeton car.

2-10—Importers' Automobile salon, New York. Fifteen exhibitors.

3-10—Automobile Show, New York; 83 cars and 266 accessory exhibitors.

6—Moline-Knight ends 336-hour test at A. C. A., averaging 38.3 H.P.

6—H. M. Leland elected president S. A. E. at annual meeting.

6—Ford to distribute $10,000,000 among employees on profit-sharing basis.

15—Benz makes 122 m.p.h. at Brooklands. Hornsted's driving beats Demogeot's record at Ormond, by making 2 miles in 0:57.99, Demogeot's record being 0:58 2-5.

15—Buick six goes 20.1 m.p.g. at Chicago. Large and small four-cylinder models make 22.5 and 17.9 m.p.g. respectively.

20—Safety First Society organized.

21—American Electric Car Co., $1,500,000 capital, organized in Chicago to take over Argo, Brock and Borland-Grannis companies.

22—85,000 commercial vehicles in use in U. S. with 274 makers.

24-31—Chicago Automobile Show; 87 cars and 266 accessory exhibitors.

26—National Automobile Chamber of Commerce, Inc., christened.

27—Nobby Tread patent declared void. Court decides that knobby tread does not infringe Stafford.

27—Cyclecar Manufacturers' National Assn. formed at Chicago.

February

10—Exports for 1913, $27,029,451; 25,880 passenger cars and 1,009 trucks; $3,325,462 over 1912.

10—Russell-Knight motor averages 35.6 H.P. in 300-hour test at Toronto.

13—Paige-Detroit M. C. Co. moves into new factory.

16—Mitchell sells wagon business. Adds $2,700,000 to automobile capital.

21—Splitdorf Electrical Co. takes over control of Apple Electric Co.

28—Pullen wins Grand Prix in Mercer, 77.2 m.p.h., 403 miles.

29—De Palma wins Vanderbilt in Mercedes, 75.5 m.p.h., 295 miles.

29—Detroit builds 35,900 cars in February. A new record.

March

2—Supreme Court decides that makers cannot fix retail prices.

3—Argo Motor Co., Inc., to build $295 car.

8—Palmer & Singer Mfg. Co. files petition in bankruptcy.

7-14—Boston automobile show opens with 90 car exhibitors.

9—Kardo Co. organized for patent purposes, $1,000,000 capital.

10—U. S. has 1,253,875 registered cars, an increase of 243,392 over 1912.

18—F. P. Porter leaves Mercer to build own car.

18—Singer Motor Co. organized with $175,-000 capital.

19—George Westinghouse dead.

28—E. Y. Knight patents double-sleeve motor.

April

9—J. Ellwood Lee, of Lee Tire & Rubber Co., dead.

13—Entz Corp., $3,000,000, to build cars with electric transmission.

15—Prest-O-Lite wins against Searchlight at Chicago.

22—Ford production nears 600,000 cars since inception.

Industrial

May

1—Ninety-four Franklin cars average 32.8 m.p.g. in nation-wide competition. High mileage is 51.2 m.p.g.

2—Chandler Six does 24.4 m.p.g. at Chicago.

5—Ten patents assigned to Universal Rim Co., Chicago.

5—E. P. Batzell, Hudson engineer, dead.

9—Charter for new Knox company given Mayo heirs. Knox Motors Co., Springfield, Mass., incorporated for $2,500,000.

12—42.4 m.p.g. on French car trials; 18 light cars show economy in 2,000-mile test.

13—Chandler Six makes 23.7 m.p.g. in New York City.

16—180 Saxons average 34.75 m.p.g. in fuel test.

18—Stewart-Warner enjoined on Motometer patent.

19—G. A. Matthews, president Jackson Co., dead.

19—Ford declares $2,000,000 dividend.

25—Bailey electric averages 22.8 m.p.h. in Boston-New York run.

26—American Electric Starter Co., Detroit, absorbs Disco.

30—Thomas in Delage wins 500-mile race, Indianapolis, 82.47 m.p.h.

June

4—Col Charles Clifton re-elected president N. A. C. C., Inc.

5—Steinmetz declares 1,000,000 light battery-driven vehicles costing under $500 will swarm streets.

11—Sunbeam wins Isle of Man race, 56.44 m.p.h. in 600-mile 2-day race.

15—Cyclecar taxicabs planned by $500,000 Twombly Co., fixing 25-cent cost for first mile.

19—Carnation 24-hour non-stop run 29 m.p.g. in New York City.

20—Packard touring car averages 75 m.p.h. at Indianapolis Speedway for 1 hour.

20—1913 tire exports total $3,943,220.

23-26—S. A. E. opens eighth summer session at Cape May, N. J.

24—Michigan has 89,413 men employed in automobile industry.

23—Thomas H. White, founder White Co., dead.

27—Master Carbureter Corp. formed, capital $250,000.

29—Chevrolet Co. buys old Maxwell-Briscoe factory, Tarrytown, N. Y.

30—Moline Automobile Co. to build Knight motors for trade.

July

3—150,000 more cars registered in first 6 months of 1914 than same period in 1913; 1,203,770 cars, 33 states.

4—Stutz wins 250-mile race, Tacoma, 73.44 m.p.h. Maxwell wins 200-mile event, 74.28 m.p.h.

4—Lautenschlager in Mercedes wins French Grand Prix, 65.55 m.p.h. Mercedes cars take next two places. Distance, 467.5 miles.

4—Rickenbacher in Duesenberg wins 300-mile race, Sioux City speedway, 78.6 m.p.h.

5—Studebaker six averages 15.15 m.p.g. in series of five 200-mile events.

6—3,732,585 sq. ft. in Ford plant after expansion of 10 years.

7—Transcontinental Saxon reaches San Francisco. Averages 30 m.p.g. for 3,389 miles.

8—Dodge Bros., Inc., $5,000,000, Detroit, Mich.

8—Franklin shows 84.4 per cent. efficiency in test at Worcester Polytechnic Institute.

8—E. C. Patterson in Packard six makes Chicago-New York run in 41 hours.

11—Denby Motor Truck Co., Detroit, Mich., organized.

General

18—Detroit's car and truck exports in 6 months $3,154,875.

18—Stearns company adds 500,000 square feet to factory.

25—Grand Prix Peugeot with 274.6 cu. in. piston displacement makes 107 m.p.h. over 4.3-mile straightaway at Boulogne.

30—United States has 1,548,350 cars registered in first 6 months of 1914. A gain of 294,485 over same period for 1913.

30—239,902 cars from 25 Detroit plants in 6 months. Ford production 162,000.

August

1—Ford profit sharing plan lowers car prices $60.

10—Winton Motor Car Co. new name for Winton Motor Carriage Co.

11—New York Division of Electric Vehicle Assn. formed.

12—Disbrow in Simplex lowers 2-mile track record at St. Louis, 1:32 3-5.

12—Tetzlaff's Benz goes 1-2 mile in 12 3-5 seconds at Salt Lake City salt beds.

13—Michigan motor industry supports 22 per cent. of state's population.

13—Tire companies increase prices from 12 1-2 to 20 per cent.

13—Crude rubber raises from $0.70 to $1.15 in 1 week.

15—Record exports last fiscal year; 30,136 valued at $27,797,642 and $4,159,454 in tires.

17—Apple Electric Company moved to Newark, N. J.

22—Wood-wire wheel test by Automobile Club of America finished.

24—De Palma in Mercedes wins both Elgin races; 73.53 m.p.h. for 301 miles in Elgin National Trophy and 73.91 m.p.h., 301 miles, in Chicago Automobile Club cup.

30—One hundred and twenty-seven Detroit companies incorporated in 7 months.

September

1—Europe orders 1,000 motor trucks.

1—Used-car markets—Chicago Auto Trade Assn. publishes first market report.

1—Receiver for American Voiturette Co., Detroit.

3—Chevrolet Royal Mail roadster makes 27.9 m.p.g. in New York City.

8—Tire prices down to normal.

11—Buick wins Wisconsin 500-mile reliability.

12—Burman sets world's 15-mile record in 12:47, Peoria, Ill., in Peugeot.

12—Sphinx M. C. Co. buys Hart-Kraft factory.

15—Remington Motor Co. announces $495 car.

17—Cadillac announces eight-cylinder motor.

19—General Motors annual report shows $85,-373,303 gross sales.

25—Champion and Jeffery-Dewitt spark plug consolidate.

26—One hundred and sixteen Franklin sixes average 11 m.p.h. on low gear for 100 miles.

28—Chandler company declares extra 10 per cent. dividend.

29—Ford lists chassis at $410.

October

1—Stearns-Knight four for $1,750.

6—New York separator repeal law defeated.

7—Horsepower and gasoline war tax defeated by Senate caucus.

7—Hess-Bright wins bearing suit.

7, 8, 9—Motor Truck Club of America holds 4-day convention at Detroit.

9—Cole four averages over 22 m.p.g. in Indianapolis speedway tests.

12—W. H. Van Devoort nominated S. A. E. president.

12—Five hundred and forty-eight companies allotted space for National shows.
12—Maxwell earns 12 per cent. on first preferred stock. Net earnings $1,430.444.52.
15—Packard production passes 25,000 mark; 3,612 vehicles built in company's fiscal year.
19—Receiver for Premier Motor Mfg. Co.
19-20-21—Electric vehicle annual convention at Philadelphia.
23—Burman in Peugeot breaks 75-mile dirt track record, 1:08:56, Galesburg, Ill.
24—Alley in Duesenberg breaks 100-mile dirt track record, at Hamline, Minn., 1:31:30, over 65 m.p.h.
26—King has eight-cylinder car at $1,350.
27—Ray Harroun appointed chief engineer Maxwell company.
27—Owen to develop Weidely motor. Weidely Motor Co. organized.
27—Stromberg-equipped Jeffery makes 28.7 m.p.g. at Chicago.
29—United States has 1,735,369 cars registered to October 1. Gain of 203,503 over statistics July 1.

November

2—Canadian-American firms to make 36,000 cars in 1915.
5—Handley buys Marion; to reorganize company. Assets bring $120,000.
7—Two-mile speedway for Minneapolis and St. Paul. Twin City Speedway Assn. builder.
9—Pope-Hartford, with Hugh Miller and Ed. Orr driving, breaks El Paso-Phoenix record; 533 miles in 14:37, at 50 m.p.h.
9—Overland, Stromberg-equipped, makes 29 m.p.g.
9-14—Fourth American Road Congress, Atlanta, Ga.
10—Finley R. Porter announces F. R. P. chassis at $5,000.
10—Dodge $785 car out.
11—Grant six with electric system, $795.
11—Oldfield in Stutz wins Los Angeles-Phoenix desert race, 696 miles.
12—Marmon 41 averages 62.89 m.p.h. for 1 hour with five passengers and top up, Indianapolis speedway.
13—Ford increases surplus by $20,702,859.39. Total surplus, $48,827,032.07.
20—English government places embargo on rubber shipments from Far East to U. S. in English boats.
20—Up-river Para down to 64c. a pound.
23—Monroe two-passenger car, $460.
23—Chicago Stock Exchange resumes trading. Closed since July 30.
23—France buys 900 motor trucks.
26—Pullen wins Corona race at 87.7 m.p.h., 302 miles, world's record.
29—Saxon Motor Co., Detroit, leases Abbott Motor Co.'s factory.

December

1—England orders 250 Peerless trucks.
1—Saxon six, $785.
4—War tax of 10 cents for car owners in several states.
5—N. A. C. C. starts interchange of patent licenses by makers.
8—Overman Cushion Tire Co., New York City, with $150,000 capital, organized to succeed bankrupt Overman Tire Co.
8—Cincinnati court rules against Ford to maintain fixed retail prices.
9—Lozier Motor Co. declared bankrupt.
10—October exports, $3,055,351; trucks exports, 672. Gain, 593.
10—Five-passenger Reo six for $1,385.
12—New York Stock Exchange opens. Closed July 30.
12—N. A. C. C. co-operates with spring makers to stop truck overloading.
14—Metz touring car at $600.
14—American Motors Co., Indianapolis, discharged from bankruptcy.
14—Walker Vehicle Co. absorbs Chicago electric.
15—Frank E. Smith, receiver, Premier Motor Mfg. Co., to continue manufacture.
15—Chicago to have 2-mile board speedway.

Recent Court Decisions—Guest Sues Owner

By George F. Kaiser

A MOTORIST must use care to prevent a guest whom he has invited out riding from being injured, and if a guest is injured he may bring suit against the motor car owner.

A motor car owner invited a friend to go riding with him. While they were on the trip the owner drove negligently and the car hit a telephone pole and was over turned. The guest had an arm broken, his shoulder, elbow and left ankle sprained and his head cut, and also suffered severe bruises all over his body. He sued his friend the car owner for his injuries and the Court decided that the suit was proper, even though the owner was insured by a liability company and judgment was rendered in favor of the injured party for $1,750.—*Fitzgerald vs. Boyd*, 91 *Atlantic* (*Maryland*) 547.

Watch Your Policy

Texas Court decides that, even though a man broke the warranties in an automobile fire insurance policy, he may still recover, when the company's general agent waived the breach.

A motorist had a $4,000 fire insurance policy on his car, which was destroyed by fire. He brought suit against the insurance company to recover that amount. The company claimed that he had broken his policy so that at the time of the fire it was null and void. The policy provided that "It is warranted by the insured that the automobile hereby insured, during the term of this policy, shall not be used for carrying passengers for a compensation, and that it shall not be rented or leased." . . ."In the event of violation of any warranty hereunder, this policy shall immediately become null and void."

During a fair at Dallas, Tex., the motorist's son took the car, without his knowledge or consent, and used it for carrying passengers to and from the fair grounds for hire.

Although the company contended that this made the policy null and void, the Court said that it did not believe that the use of the car that way for a limited time breached the policy, as the working evidently meant that it should not be used that way continuously.

The company further contended that, as the policy contained the clause that "in consideration of the reduced rate at which this policy is written, it is understood that the property insured hereunder shall, at all times, be kept or stored in the private garage or private stable situate at 1000 South Harwood street, Dallas, Tex.; privileged, however, to operate the car and to house in any other building or buildings for a period of not exceeding 15 days at any one location, at any one time, provided the car is en route, visiting or being cleaned or repaired. All other terms and conditions of the policy remaining unchanged," and the motorist had used the car for several trips lasting more than 15 days, the policy was also null and void under this warranty.

The Court decided that, notwithstanding the fact that the policy was broken, the motorist was entitled to his insurance, because he had gone to the general agent of the company and had asked permission to go to his farm and such permission had been given him.—*Commercial Union Assurance Co. of London vs. Hill*, 167 *S. W.* (*Texas*) 1095.

Motorist Loses in Damage Suit

The fact that a motorist failed to give proof of his competency as a driver, and to show within what distance his car could be stopped, together with his failure to produce the bicyclist, who was an eye witness to the accident, caused the Minnesota Court to hold that judgment against him was proper, in a late case where a horse owner sued for injuries to the horse.

A horse was tied to a hitching post on a curb of a street in St. Paul. A few feet away, and on the other side of the street, was a covered automobile. The owner of the horse was absent 15 minutes and, on returning, found that the horse was so badly injured that he had to be killed. The owner of the horse thereupon sued the owner of the automobile for the value of the horse. The motorist showed that he had driven near the center of the street at about 10 to 12 miles an hour, and that when he was about 7 or 8 feet from the horse, a bicycle suddenly came from behind the carriage and, to avoid running down the bicyclist, he turned his machine at right angles and applied his brakes and that the pavement being wet, the machine skidded, hit the horse and injured it.

The court decided that he should have gone further and showed how competent he was to operate the machine, within what distance it could be stopped and should have either had the bicyclist in court as a witness or explained his absence.—*Whitewell vs. Wolf*, 149 *N. W.* (*Minnesota*) 299.

Balanced Intake in Rotary Motor

Bournonville Single Rotary Sleeve Performs Functions of Exhaust and Inlet Valve—Operated for 4,000 Miles

EUGENE M. BOURNONVILLE, who was one of the pioneers in oxy-acetylene welding in America, has invented a rotary valve engine and placed it in a chassis and after having submitted it to a 4,000 mile test is now making negotiations for its sale. As in other rotary valve motors which have recently been placed on the market, there is no difference from ordinary engine construction. In making up the experimental job a Fiat power plant was used, the only alteration being in the top of the cylinder head. Here a rotary cylinder extends horizontally the length of the motor and performs the functions of the inlet and exhaust valves.

A housing above the cylinder head contains the rotating cylindrical valve, and it is in the arrangement of the gas passages in the housing and in the valve itself that Mr. Bournonville claims to have overcome the difficulties which have heretofore been found in rotary valve motors.

Referring to Fig. 1 the top of the cylinder is seen at *A* and a passage or port leads from it vertically upward at *B*. This port serves as the means of communication between the valve above it and the cylinder below and hence offers a common passage for the exhaust and inlet gases. The valve itself is denoted by *C*. It rotates in the housing *D*. The intake manifold is a unit with the housing at *E* and the exhaust port is at *F* leads into the manifold *G*. This entire assembly is surrounded by the waterjacket *H*.

Referring to the transverse section of the motor at Fig. 1. the inlet manifold *E* runs the entire length of the motor and communicates through the ports *L* to the corresponding openings in the valve over each cylinder. In the position shown the cylinder is receiving its charge under suction stroke, the gas entering at *L* passing through *M* and thence through the opening *B* into the cylinder. As the valve turns on its axis the port is closed by the solid portion *N* covering the opening *B*. This holds the compression and after the firing stroke covers the inlet port *L* while the next opening portion of the valve *O* affords a passage from the cylinder through *B* to the exhaust manifold *G*. The positions of the valve for inlet, compression, firing and exhaust are given in Fig. 5.

Thus far the action of the valve is similar to other rotary valves. The big difference is in the means of distributing the

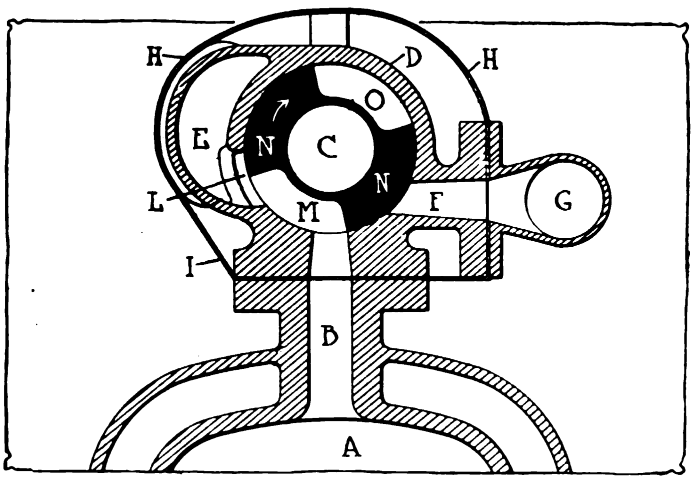


Fig. 1—Transverse section through Bournonville rotary valve motor

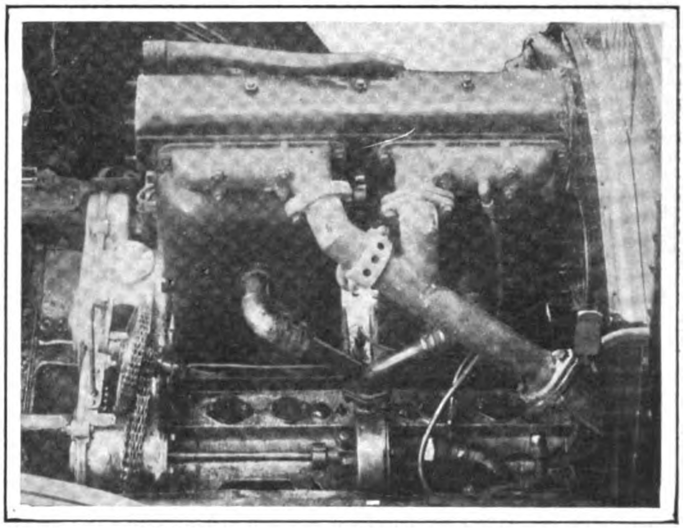

Fig. 2—Exhaust side of engine, showing mounting of valve housing

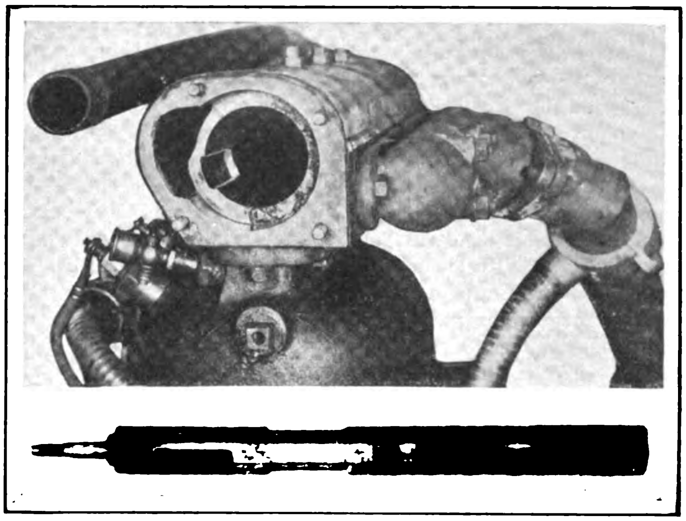

Fig. 3—Mounting of the valve housing and, below, the valve withdrawn

intake charge. The arrangement is such as to provide a heat balance and a friction balance at each cylinder, thus securing uniformity in the performance. The inlet manifold *E* extends the entire length of the valve housing passage. It communicates with the port *L*, which also extends the entire length of the housing, at each end. This offers, in effect, a long tube open at either end with gases entering from both sides. At four points in the length of this pipe there are openings corresponding to the passages to each of the four cylinders. Since the gases enter from the two sides simultaneously the average temperature of the gas will be the same at each cylinder because, if the gas gained one heat unit for each unit of length traveled and it had to travel two units from one side and eight units from the other it would have gained ten units; or, if it had to travel five units from each end it would still have gained ten heat units. This holds true for any point from which the gas is taken, in the length of the pipe. A friction balance is maintained in the same way. The distance that the gas has to travel is always the same no matter for what cylinder and hence the amount of frictional resistance to be overcome is constant.

Another effect secured by having the intake passage *L* open at both ends is that the gas is continually see-sawing backward and forward, giving a wiping action of the gases on the exposed surface of the rotary valve. This action is what the inventor claims to be the agent which keeps the valve free from carbon and hence eliminates cutting. On the engine which has now run 4,000 miles there is no sign of cutting visible. There is no carbon deposit on the exterior surface of the valve although in the ports *M* and *O*, there is the same kind of carbon caking that would be noted in the ports of a poppet valve motor. These ports, which are dark on account of the carbon deposit, can be seen in the accompanying illustration Fig. 3 and it will be also noted that the bearing surface of the valve retains its polish. A method of driving this valve is shown in Fig. 6. It is by silent chain from the crankshaft through the reduction gear as shown. The timing gear case in the illustration is not required in the rotary valve motor but remains in its position through the fact that this is a rebuilt job. In the tests that were carried out the old camshaft was left in place although turning idly.

With the two ports *M* and *O* the rotary valve is driven at one-fourth crankshaft speed. If it is desired the number of these could be increased to three or four with consequent reductions in the speed of the drive. This would not be feasible on smaller motors. The dimensions of the test motor illustrated are 4 15-16 by 5 15-16.

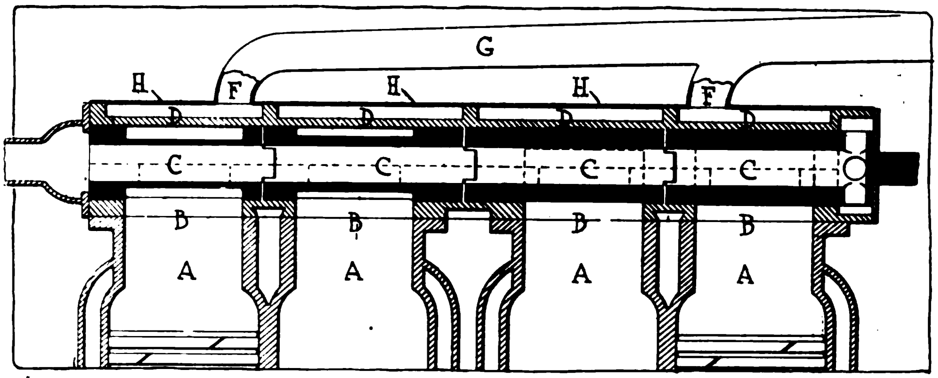

Fig. 4—Longitudinal section through Bournonville motor, showing valve in four parts

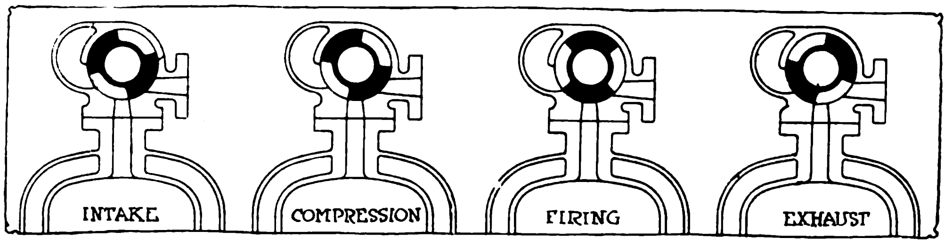

Fig. 5—Positions of the rotary valve for intake, compression, firing and exhaust

Valve Timing Orthodox

The timing of the rotary valve does not differ materially from that of ordinary poppet practice. The intake opens 15 degrees after upper dead center and closes 20 degrees after lower dead center. The exhaust valve opens at 45 degrees before lower dead center and closes 5 degrees past upper dead center. This gives a 10 degree pause between the exhaust closing and the intake opening with which a vacuum is created in the cylinder to promote a rapid inflow of gas on opening. The area of the ports is the same for intake and exhaust being 2.25 square inches with a length of 4.5 inches and width of .5 inches. Compression is 72 pounds per square inch.

In manufacture the cylindrical valve is made with .002 inch clearance in its housing. The housing itself being of large diameter can be ground with a cylinder grinder and the sealing of the valve is accomplished by the oil film in the small amount of clearance. The oil itself is the thinnest possible to avoid the loss of power required through shearing a heavy oil film. In taking down the engine after a difficult 100-mile run during which the car was driven by a representative of THE AUTOMOBILE a liberal coating of oil was found along the entire surface of the valve. Oiling on the experimental engine insofar as the cylindrical valve is concerned is taken care of by the suction of the cylinder. It is purposed on the permanent job to install a mechanical oiler. Another important feature which will be changed in the permanent manufacturing job is in the making of the valve housing and waterjacketing integral with the cylinder casting. This will reduce height and permit of more advantageous jacketing.

The elimination of moving parts is the chief advantage claimed. The valve timing once set remains constant and the valve itself can be taken out for examination in 10 minutes. As the valve is made in four parts as shown in Fig. 2 the amount of warping for each part should not be of any effect.

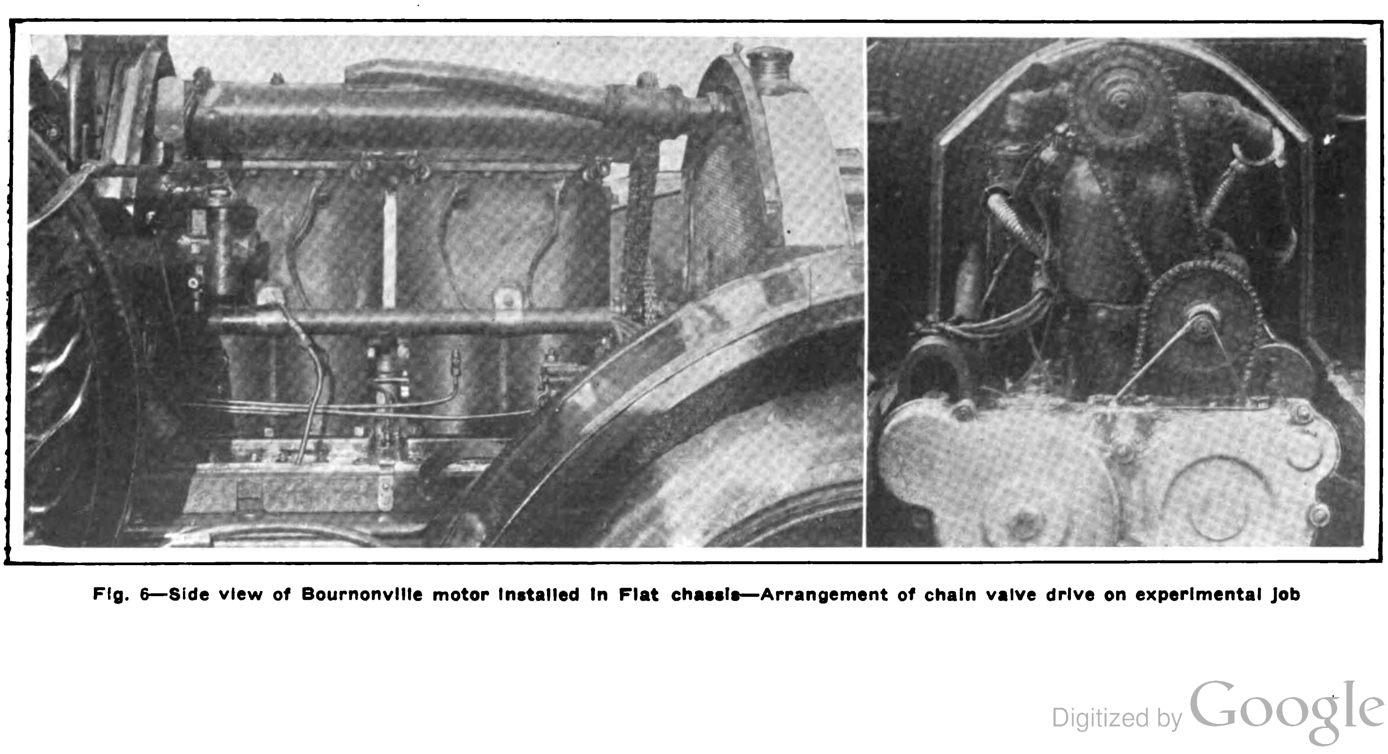

Fig. 6—Side view of Bournonville motor installed in Fiat chassis—Arrangement of chain valve drive on experimental job

Newcombe's Law Applied to Motors

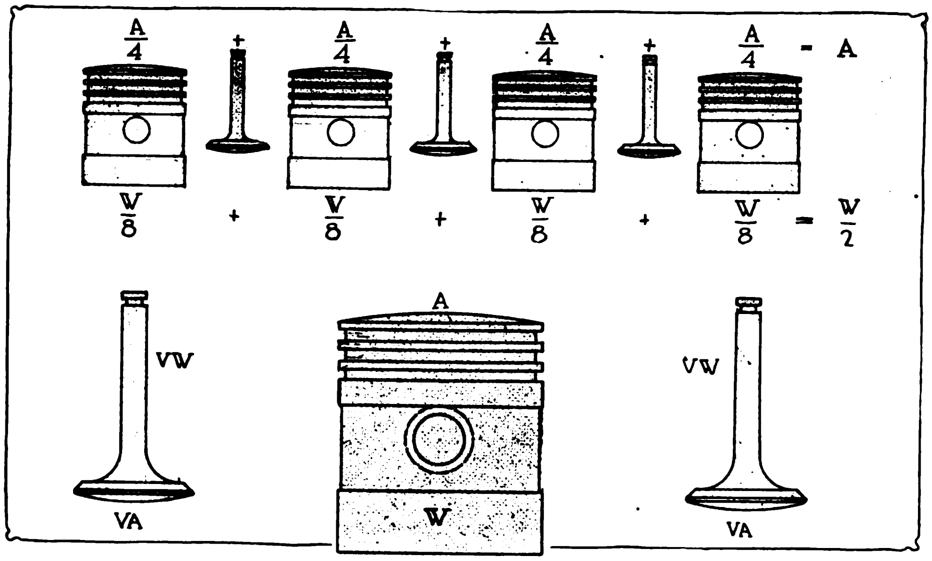

Fig. 1—Illustrating Newcombe's law. Above—Four pistons each half the size of the large piston shown below or 3 inches in diameter. This shows how by decreasing size an equal piston area is obtained while the reciprocating weight is thereby cut exactly in half. Below 3 inches mechanical difficulties limit carrying the law to the extreme

Piston Friction in Multiple-Cylinder Types Compared—Rigidity a Factor in Longevity

By William B. Stout
Chief Engineer, The Scripps-Booth Co.

DETROIT, MICH—Editor THE AUTOMOBILE:—The high-speed motor is a coming proposition. Slow-speed motors have proved grossly inefficient compared with the small-bore, high-speed types of Europe.

A high-speed motor may be as long lived as a slow speed. The four-cylinder motor in racing has proved the best high-speed automobile motor to date. The new eight-cylinder type of motor is acclaimed with reason as a better high-speed possibility than are six-cylinder constructions.

Rigidity a Necessity

Rigidity is the basis of engineering construction in high-speed motor design. Balance is the secret of power and r. p. m., and the chief reason for the long life of high-speed motors. Small bore and light pistons are, in turn, a chief secret of balance and form the primary basis for the very high degree of efficiency which is obtained in motors of high-speed type.

It is no longer good engineering, or good sense to judge the power of a motor by its bore and stroke. A 2 1-2 by 4-inch motor may give 6 horsepower actual or it may give 18 horsepower. R. p. m. with bore and stroke is not an entire basis of judgment. A motor may be able to turn up to 3,200 r. p. m. on the block and yet its power curve may show a decided drop in power at 1,000 r. p. m.

Efficiency the Aim

The chief aim of the high-speed motor is efficiency. If one takes a 12-horsepower motor and runs it at twice the speed with the same efficiency he will get 25 horsepower from the same bore and stroke. The aim of the up-to-date, high-speed motor designer, then, is to obtain the same efficiency, long life and freedom from vibration at 2,500 r. p. m. that present motors show at 1,200.

Every indication points toward the high-speed motor as the real innovation of 1915, public interest toward this type of motor having begun with the success of the Peugeot in the Indianapolis race in 1913.

With the coming of the eight-cylinder motor as a large probability for 1915, interest in high speed types has been doubled, as the eight-cylinder has possibilities as a high-speed, long-life motor.

Six Speed Limited

The six cannot attain to real high speed, due to crankshaft limitations.

A high-speed motor can be made as long lived as a slow-speed motor and can be run with as little overhauling and expense. The matters of long life and small wear are almost entirely questions of the rigidity of parts rather than their mere capability of transmitting the amount of power which goes out of the motor. Shaft diameter, for example, is figured largely, not from its power-transmitting capabilities, but its stability and freedom from whipping at the r. p. m. for which it is intended. Motors whose power could be transmitted by a 1-inch shaft are fitted with crankshafts over 2 inches in diameter and of the highest grade steels. Crankcases are stiffened. Castings throughout are watched to prevent internal vibration in the motor, which will tend to misalignment of bearings or distortion-friction in any of the moving parts. These conclusions point toward the eight V-type

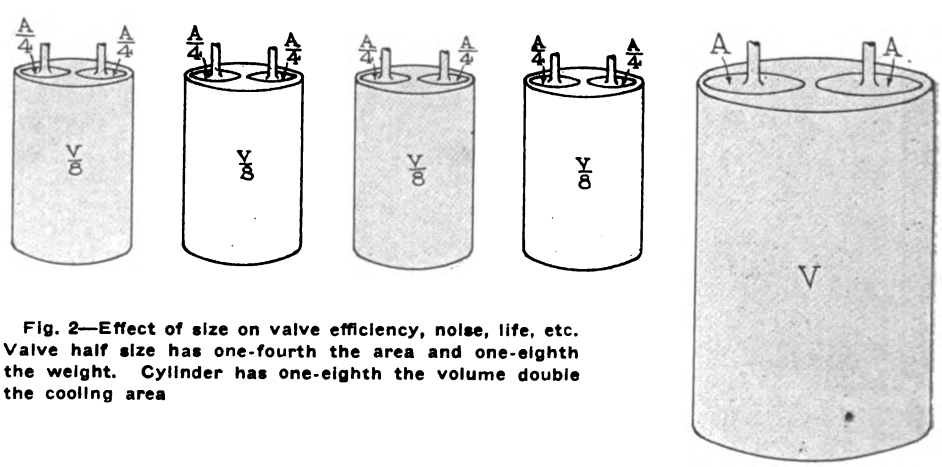

Fig. 2—Effect of size on valve efficiency, noise, life, etc. Valve half size has one-fourth the area and one-eighth the weight. Cylinder has one-eighth the volume double the cooling area

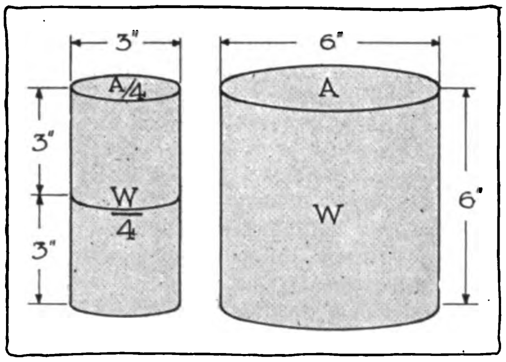

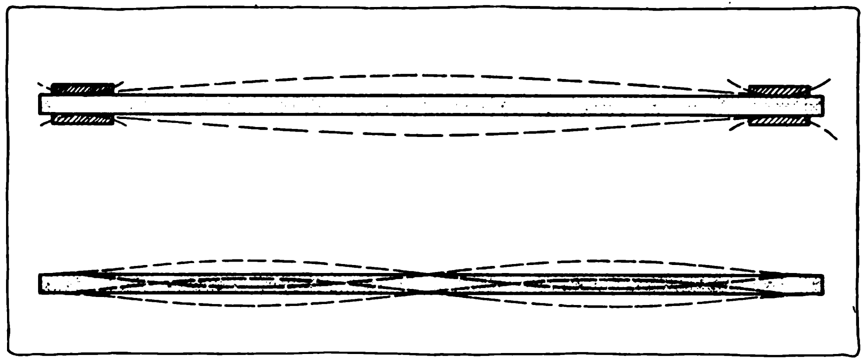

Fig. 3—Left—Theory of 2 to 1 stroke ratio. Fig. 4—Right—Above—Critical speed in shafts, the limitation of most American cars, the basis of metal fatigue. Below—Second critical speed with center node

motor as the eventual motor for cars requiring above 3-inch bore.

It would be practically impossible to build a high-speed six, in the writer's opinion, of greater than 3-inch bore, and even then the question would be one of the length of life of crankshaft bearings. A two-bearing crankshaft is preferable for high-speed work, from the standpoint of manufacturing cheapness, for a three-bearing shaft needs to have each web counterbalanced, and again because this type of motor is shorter and lighter in weight. The large size of the crankshaft insures the rigidity.

If a crankshaft of certain size is rigid on a four-cylinder it is doubly rigid if applied to an eight of equal cylinder capacity, for each explosion is of smaller moment, and the reciprocating parts are very much lighter in the eight. This statement holds good for all motors above a bore in the neighborhood of 3 1-2 inches. In smaller sizes, mechanical limitations do not allow the same laws to hold.

The smaller the bore, the more feasible, commercially, becomes the overhead valve. For really high-speed work where greatest amount of efficiency from bore and stroke is aimed at, overhead valves are a necessity. These valves as constructed in modern small bore motors, are even quieter than L head motors of the larger type and are especially accessible.

The following discussion covers points governing the main constructional ideas of high-speed motor construction:

Thinks 3-Inch Ideal

There is a basic engineering law which points toward the small-bore motor as an eventual type for all internal combustion engines where weight is a factor. Maximum and minimum formulas show that the most efficient motors, all things considered, probably will have a bore of around 3 inches.

All arguments to date in favor of six and eight-cylinder constructions have been based on purely theoretical assumptions, but few have taken into consideration the mechanical difficulties and limitations which hedge any theory in its application to automobile motor practice. There are certain things which are as basic in their application and as inevitable in their result as the fact that two plus two make four. The law governing motor size and pointing toward future development is as basic as this and was seriously brought to public notice by Simon Newcombe in his now famous mathematical proof that aeroplanes would never fly. The law which he stated exists, but the aeroplane designer, approaching the flying machine from a different angle than what Newcombe had in mind, overcame the law by mechanical construction which made it an assistance instead of a detriment.

Newcombe's Law

Briefly stated and explained, the law is this: IF YOU MAKE A THING HALF THE SIZE IT HAS ONE-FOURTH THE SURFACE, BUT ONE-EIGHTH OF THE WEIGHT.

ALL SURFACES ARE MEASURED BY TWO DIMENSIONS, LENGTH AND BREADTH; VOLUMES ARE MEASURED BY THREE DIMENSIONS, LENGTH, BREADTH, AND THICKNESS. IF YOU DECREASE AREA ONE-HALF YOU DECREASE TWO DIMENSIONS AND THE SIZE IS ONE-FOURTH. IF YOU DECREASE VOLUME ONE-HALF YOU DECREASE THREE DIMENSIONS AND THE MASS OR WEIGHT IS ONE-EIGHTH. THIS BRIEFLY EXPLAINS WHY HIGH-SPEED MOTORS ARE DOING SUCH REMARKABLE WORK AND AT THE SAME TIME SHOWING SUCH SURPRISINGLY LONG LIFE.

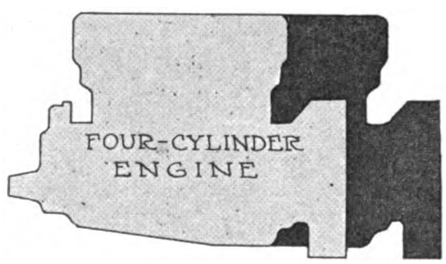

Fig. 5—Diagram showing the added weight in six-cylinder motor construction

Fig. 1 shows this law as applied to piston size, for example.

Below is shown the piston of a large bore motor—say 6 inches. This has an area on top of A, it has a weight together represented by W. The power of the motor is determined by three factors: the area A, length of the stroke L, and the r. p. m., R. It will be shown that the size of the piston has a great influence on all three of these factors and that the smaller the piston—within mechanical limitations—the more efficient.

Applying the Law

Above are shown four pistons, each half the size of the big piston, or 3 inches in diameter. The area of the piston on top in each case is $\frac{A}{4}$ since the area of each piston is 1-4, the area of the original. The weight in each case is $\frac{W}{8}$. The four pistons together have the same top area as the big piston or A, but the sum of their weights is one-half the weight of the original piston or $\frac{W}{2}$. Thus, by decreasing size we have obtained an equal piston area and have cut the reciprocating weight exactly in half. Since the same law applies to connecting rods it can be followed all the way through, it being acknowledged of course that below 3 inches, mechanical difficulties of construction come in which limit carrying this law to the extreme.

The internal friction on the four pistons would be the same as in a single big piston, as the side area of all four is equal to the side area of the original big one. The angularity of the connecting-rod would presumably be less with the small piston than with the large, as the light weight would not make the matter of keeping the angle small of so great moment. This law as explained in regard to pistons will at once explain the advantage of the long-stroke motor for high-speed work and an advantage which I think has not yet been explained

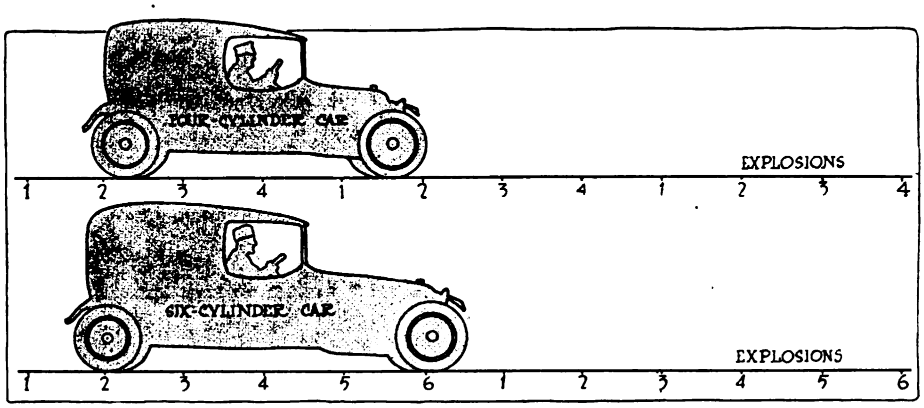

Fig. 6—Flexibility is shown by the number of explosions per mile whether the motor is four or six and is the result of gear ratio, not the number of cylinders. A high-speed four approximates a medium-speed six in performance

satisfactorily by any line of engineering argument heretofore published.

Having found the advantage of small piston size and presuming that the 6-inch bore piston in the first place was fitted to a 6-inch stroke engine—according to old-time practice—there will immediately be seen a reason for the long stroke in connection with the small piston, that the volume ratios may be kept as nearly as possible the same. In actual practice few motors are built in this country with two ratio stroke, but just what ratio is best has been ably handled in former articles. By shortening the bore-stroke ratio, however, little is lost for with pistons of half the weight the r. p. m. can be run up to a point where the piston's speed rate is very much higher than it was in the first case with the large piston. This ability to make higher speeds with the reciprocating parts very much more than compensates even should the stroke be decreased almost in proportion.

It will be noticed in Fig. 2 that our cylinder volume has decreased in proportion to surface enormously. Whereas the large cylinder has a volume W and a certain outer surface or cooling area, A the small cylinder has one-fourth the cooling area A, but only one-eighth the volume V of gas to cool, providing the cylinder length has decreased in proportion.

Fig. 3, however, shows the motor with the long stroke; this has one-fourth the piston area but the same stroke as in the first case, so that the volume of the small cylinder is one-fourth of the original. In this case, four-cylinders would show the same cubical capacity as the original one-cylinder at the right. The four-cylinder motor, however, as explained, shows but one-half the reciprocating weight of the single-cylinder, large-bore motor of the same piston area and the same volume.

It does not require any argument further to show that the maximum efficiency motor from this law alone must be a motor of high r. p. m. and small bore.

There are other reasons in the mechanism which allow the motor to make this r. p. m. beside that of weight of reciprocating parts. Fig. 2 illustrates Newcombe's law of sizes as applied to the complete cylinder, showing cylinders of 3 and 6-inch bore fitted with valves of one-half the cylinder diameter and in the head.

The smaller cylinders have one-eighth the volume of the big cylinder but the valves are one-fourth the area so that the valves in the smaller motor have just one-half the gas to handle per square inch of valve area that the big motor has, so that the smaller the cylinder the greater carrying capacity the valves will have.

While the small cylinder holds one-eighth of the gas in its volume it has one-fourth the cooling surface, so that theoretically at least twice the number of heat units can pass through the cylinder per minute.

Overhead-Valve Type

Engineers agree that the theoretically ideal valve construction is the overhead type. They admit from 12 to 15 per cent. more power from the same bore and stroke as with an L-head. The overhead valve in the large-bore motor is too noisy, however, for commercial use.

Valves in a small-bore motor can be built in the head and still be wonderfully quiet, as the valves in the smaller cylinder shown weigh one-eighth as much in the big cylinder. This less weight added to the lesser area enables the designer to fit valve springs much lighter in tension per square inch of valve area than in the big motor—less than half in practice. The possibility of overhead valves in a small-bore motor, however, adds greatly to its efficiency value. The same discussion of valve sizes applies also to L-head, block motors where the close proximity of the cylinders limits the size of the side-by-side valve. The use of small bore increases the valve carrying capacity with the same diameter.

In calculating the horsepower of a motor one cannot judge by the bore and stroke. A motor from which we obtain 12 horsepower the foreigners increase to 30 or 40 by the application of high speed principles, and one must consider r. p. m. as a basic factor in judging any motor.

Long life in a motor depends very largely upon the rigidity of its parts. This term rigidity should not be confused with the term strength, for by strength one thinks of immediate breakage whereas rigidity is a factor toward decreasing vibration and stress on bearings and working parts. There are many motors today which can turn over at 3,000 r. p. m. but whose practical working road speed is not over 900 r. p. m. The parts sustaining the moving factors of the mechanism are not of sufficient rigidity to allow bearings, oiling systems, couplings, etc., to stand the continued vibration or distortion.

Crankshaft's Critical Speed

Practically every motor of limited commercial r. p. m. can figure its limit of r. p. m. from the *critical speed* of the crankshaft. Every shaft, no matter what its size, has a critical speed, as shown in Fig. 4. The diagram is of a support on two bearings a considerable distance apart. One can rotate the shaft between these bearings slowly and it will work perfectly and last forever. As the speed increases, however, centrifugal force develops a whip at the center of the shaft, induced by the natural deflection of the shaft under its own weight between centers. This starts the center of the shaft whirling like a child's skipping rope, as shown by the dotted lines, and the speed point at which this whipping develops is known as the critical speed. If one gets above this speed a shaft will again find its center until at another point of higher r. p. m. it finds a second critical speed, and here it will be found that there is a node at the center of the shaft and a whipping in two directions from it, as shown in the lower sketch of Fig. 4. This indicates that a center bearing on a shaft may double possible motor speed with the same diameter crankshaft.

Crankshaft critical speed is the answer to the failure to date of the high-speed, six-cylinder motor of commercial type. For high-speed work a short crankshaft is necessary.

Every discussion which the writer has seen favoring the six and eight-cylinder types over the four has been taken largely from the standpoint of even-power torque. This is not the basic reason for the eight-cylinder motor or the four and not its chief advantage over the six. The writer prefers the four or the eight for reasons of mechanical limitations which no one has been able to overcome in the six.

The first deficiency of the six is its extra length and its extra weight, so that while one adds power in building a six he does not add equivalent power per pound, for the r. p. m. possibilities of the six are far below that of the four as a commercial-design proposition.

Two-Bearing Four

A four-cylinder motor can be built with two bearings on a very short crankshaft of large diameter. The extra diameter of this crankshaft makes little difference, as it is largely flywheel weight. This motor is a well-balanced motor for without the center bearing the crankshaft itself is in rotating balance and hence does not throw side stress on the bearings through its centrifugal deficiencies. In the six there cannot help but be a certain amount of distortion at high speeds which throws the engine out of balance. It is almost impossible to build a six cylinder motor which will not show critical speed in its crankshaft.

Supposing that in Fig. 4 one end of the long shaft shown were held in a vise. Supposing a wrench or crank were put on the other end and a 1,000-pound load was suddenly dropped on the end of this crank. There would be a certain amount of twist in the length of this shaft no matter how rigid, this twist depending on the leverage, the length of the shaft and diameter. A shaft one-third shorter would show far less twist effect with the same load and hence the shorter the shaft fitted to a high-speed motor the less will be this twist of the shaft. *This torque twist is not to be confused with critical speed and shaft whipping as this is another condition.*

In a six of fairly large size to throw one piston out of line for 100th of an inch at high speed is enough to create very great internal stress in the motor, and at high speeds this is felt in all six-cylinder motors. The six in large sizes through its mechanical crankshaft limitations must be a slow-speed motor.

Answering the argument of even-power torque in favor of the six-cylinder motor, there is no difference between the power torque of a six or four in its effect on the car *provided the number of explosions per mile be the same.*

A high-speed four, that is a four on a comparatively low gear ratio giving, say, 6,000 explosions per mile, will show the same flexibility and low speed running as a six, and in far less weight, provided the six is higher geared to give the same 6,000 explosions per mile. The extra two cylinders of the six are to give greater motor flexibility and the six is more flexible at slow speeds, but by making the four with a gear ratio giving the same number of explosions per mile as the six the four does not have to run so slowly to drive the car equally slow with the six.

The deficiency would seem to be therefore at the higher speeds, for ordinarily a low gear means a hindrance of maximum speed possibilities. With the new fours this is not the case. A small-bore motor can turn over so much faster maximum than a six of large bore that it more than makes up for the deficiencies of the low gear ratio. Small-bore, well balanced fours with big crankshafts and rigid construction, with pressure feed oiling, as in European motors, can keep up from 2,500 to 3,500 r. p. m. for long periods without undue strain. There are more periods of stress, it is true, as there are more revolutions and more explosions, but each one is far less than in the slower speed types.

Eight Outlook Bright

Since it is hard to make a high-speed six, and since there is advantage in the modern high-speed motor, the outlook for the eight is very promising. With large cars where a bore of 3 inches or thereabouts is not large enough it is very probable that the eight-cylinder will come into prominence. This motor can be built shorter than the four of equal power and lighter. Through the law explained at the beginning of this article THE PISTONS OF THE EIGHT WEIGH MUCH LESS THAN THE PISTONS OF THE FOUR OF EQUAL CYLINDER CAPACITY. The thrust per explosion will be less and the centrifugal force of the moving parts less so that THE SAME SIZED CRANK WILL GET LESS WEAR THAN IN THE ORIGINAL FOUR. The flywheel weight can be less on account of more even torque and because THE PISTONS AND RODS FORM PART OF THE ROTATING WEIGHT.

With the lighter moving parts the r. p. m. possibilities of the eight should lead to wonderful speed performance, making a low gear ratio possible and quick acceleration. For small cars the high speed four motor is wonderfully efficient and reliable. For big cars the eight has a great possibility. For slow speed motors the six will continue to be popular.—WILLIAM B. STOUT, Chief Engineer, Scripps-Booth Co.

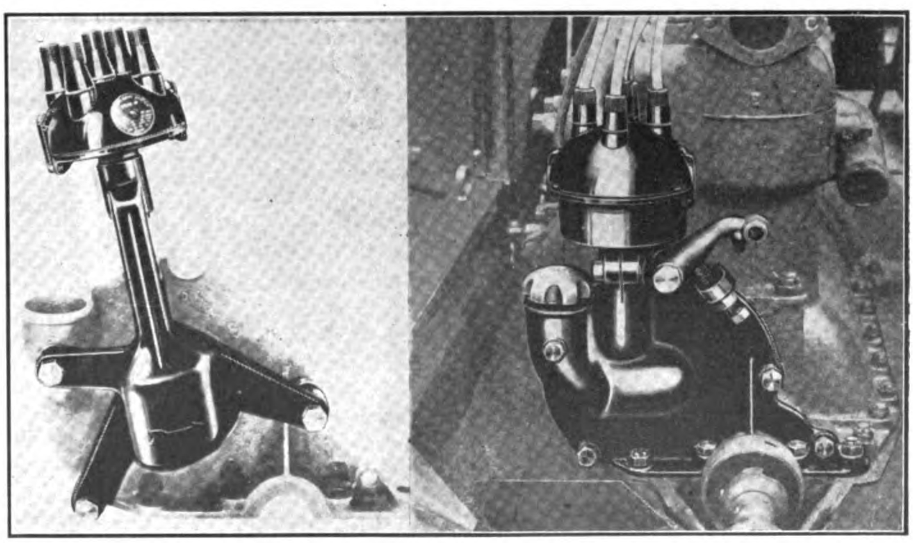
Ford Unisparker Has Automatic Advance

TO drive without thinking about the spark advance, to crank the motor without danger of a back kick and without spinning are the features offered by the adaptation to the Ford car, of the model K-2 Unisparker made by the Atwater Kent Mfg. Works, Philadelphia, Pa.

The device is mounted in a special gearcase cover which replaces the regular one and which can be attached without any fitting. Retard of the spark when cranking the motor is automatic and when the speed of the motor increases the spark advances, thus eliminating the hand control. The spark lever is removed as it is not needed. Spark advance is maintained up to 2,400 revolutions per minute and this range is ample for Ford requirements.

The price of the new instrument is $28, which was formerly the figure at which the type H instrument for Ford cars sold at. Recently the price of the type H was reduced to $22. Either of these models costs $2 more when a kick switch is furnished.

Current is supplied by a 6-volt storage battery or a six-cell dry battery, and it is stated that a set of dry cells will last 2,000 miles. The Ford magneto may be used for lighting.



At the right is illustrated the new Ford Unisparker with automatic advance. At the left is the instrument as made without automatic advance

Reasons for Advancing Spark Lever

EDITOR THE AUTOMOBILE:—In answering a question in the issue for December 10 you say:

"The necessity for advancing the spark is brought about by the fact that it takes a definite time to produce the spark, that is, from the instant the breaker points separate on the magneto until the spark occurs in the cylinder a small amount of time is consumed."

Now I know that this is the popular explanation for the necessity for advancing the spark, yet when we remember that the electric current travels several thousand miles in a second and that the distance from the breaker points to the spark plug is at the most only 3 or 4 feet it seems to me that this reasoning does not satisfy. Although I am a motorist of 10 years' standing I have never yet heard or read of a good explanation of this matter of spark retard and advance and the fact that the question of automatic or hand control is far from settled shows that this matter is not understood.

2—Any information regarding this question of spark advance will be appreciated. For instance, can you explain why advancing the spark so that the ignition occurs before the highest point of piston travel increases the power when the motor is speeded up?

East Canaan, Conn. D. C. CANFIELD.

—1—It takes time to produce a spark because of certain secondary effects that occur when a circuit is closed or opened. Suppose we have a spark coil and close the circuit. It is natural to believe that immediately the flow of current would rise to its full value, but it does not, for the reason that the flow of this current is opposed by a counter electromotive force which the current itself generates. This counter electromotive force, or voltage, however, gradually dies down so that the current eventually rises to its full value.

Magnetic Field Set Up

It is common knowledge that when a current flows in a wire that the space surrounding the wire is magnetized, or to use the technical term there is a magnetic field around the wire, the greater the current flowing the more intense this field. It is also well known that whenever there is a relative movement between such a magnetic field and *any wire within the influence of the field* a voltage is induced in this wire and a current flows. This principle is used in generators by moving the wires on the armature with respect to the field magnets, and in an induction coil this relative movement between secondary coil and primary magnetic field is produced by suddenly increasing or decreasing the strength of the field. The increase or decrease, as the case may be, induces a current in the secondary.

Since the primary magnetic field when it increases or decreases in strength causes a current to be generated in the secondary, it is only natural that this change in field strength will also produce a voltage in the primary winding itself, self-induction is what it is called. This voltage is in the opposite direction to the line voltage which is causing the current to flow. Therefore, when a current starts to flow it cannot rise to its full value immediately. It starts out with a rush when the circuit is closed but this causes a large back voltage to be generated; little by little the *rate* of current increase falls until the current reaches full value.

There is also some delay when the spark is produced by breaking the circuit due to self-induction in the secondary circuit and mutual induction in primary and secondary, but the delay is not so great because the flow of current due to the back voltage in the primary circuit is in the same direction as the flow due to the line voltage.

2—Since it does take an appreciable amount of time to produce the spark after the circuit has been closed or contact broken according to the system employed, it is necessary to advance the spark lever as the speed of the motor increases in order that the spark may be produced at exactly the same instant.

Why Advance Is Required

When the motor is running slowly, say 300 revolutions per minute, it takes a comparatively long time for the piston to complete its cycle and therefore if the spark is to occur just as the piston reaches top dead center the circuit breaker does not have to open much sooner. If it takes .01 second for the production of the spark after the breaker points separate, then the spark lever must be so set that the breaker points will open .01 second before upper dead center is reached.

Suppose now that we increase the motor speed to 3,000 revolutions per minute, the piston now is moving ten times as fast as formerly yet it takes just as long for the spark to be produced. Therefore if the spark is to occur at the instant the piston reaches top dead center, the spark lever must be advanced so that the breaker points separate long before dead center is reached.

So much for the spark lag; but it also takes a small amount of time for the charge to burn, and although this interval may not be appreciable when the motor is running slow it must be taken into account when the motor is running at full speed; therefore the spark must be advanced still further if the charge is to be completely ignited when the piston reaches top dead center, and since maximum pressure rise occurs somewhere near the point at which the burning of the charge is completed and since it is advisable to have the point of maximum pressure attained at about the time the piston reaches top dead center if best power and economy are to be obtained, it is best to have the combustion of the charge about completed when the piston reaches top dead center.

Reason for Vibrators on Ford

Editor THE AUTOMOBILE:—1—What is the address of the Simms Magneto Co.?

2—Since the Ford magneto produces an alternating current, why is it not possible to discard the coil vibrator in its electrical system?

3—Again, why will not the four-point timer, of the conventional type, in a system with four non-vibrating coils produce results like a circuit breaker, a non-vibrating coil and a distributer system?

Rices Landing, Pa. J. A. SHARPNACK.

—1—Simms Magneto Co., Bloomfield, N. J.

2—It would be possible to discard the vibrator but if this were done only one spark would be produced each time the circuit was closed instead of several.

3—For the sake of clearness the two systems are illustrated in Figs. 1 and 2. The main reason that the four-unit coil non-vibrating system, you suggest, will not work satisfactorily is that a weak spark is produced when the primary circuit of any coil is closed, a much stronger spark being produced when the circuit is broken—which is the method employed in the breaker system. Also with the breaker the sparks are much more accurately timed.

With the four-unit, non-vibrating coil system the spark is produced as follows: The timer closes the circuit, and the current builds up to full strength in the primary circuit. While the current is increasing in strength the magnetic lines of force around the coil (due to the current) are also increasing in number. The increasing strength induces a current in the secondary, the exact amount of which is dependent on the rate of current increase in the primary. As previously stated, the current in the primary rises to its maximum value comparatively slowly, due to various electrical effects.* It is seen that the voltage generated in the secondary must be greater when the speed at which the lines of force multiply is greater, but this rate of increase when the circuit is closed is limited by a phenomena known as induction.

Now when the magnetic field of the primary coil is decreasing in strength, a voltage is also induced in the secondary. In other words, either an increase or decrease of magnetic field strength will produce a voltage in the secondary. By breaking the circuit the reduction of field strength is exceedingly rapid. The rate of decrease is much more rapid than the rate of increase under the most favorable circumstances. The result is that this increased rate produces a higher voltage in the secondary, and due to the higher voltage a greater current flows, and the larger the quantity of current the hotter the spark.

In the breaker system, you mention, the circuit is broken to produce the spark and therefore this is superior to the four-unit coil, with timer system.

You have failed to recognize, apparently, that the number of coils really has nothing to do with the proposition. You might have a single coil with a single contact timer and then place a distributer in the secondary circuit to deliver the sparks to the right cylinders in turn.

Hydrometer for Anti-Freezing Solutions

Editor THE AUTOMOBILE:—I have a 1913 Cadillac car. When the cold weather first started I put two quarts of alcohol and one pint of glycerine in the radiator and whenever the car is filled, I mix 25 per cent. of alcohol with 75 per cent. water. We have had many warm days since the mixture was put in the radiator and undoubtedly the alcohol evaporates more quickly than the water. Therefore I do not know at present how much alcohol there is in the radiator.

Is there any way of ascertaining this from time to time so as to know whether to put more alcohol in or not?

Buffalo, N. Y. CHARLES HINES.

—If there has been no leakage in the cooling system, it will be sufficient to add alcohol because the amount of water that has been evaporated is negligible, for the reason that alcohol has a much lower boiling point than water—and of course, there is no danger of the glycerine evaporating.

But if some of the solution has leaked out and you know the specific gravity of the original mixture you may easily determine whether to add alcohol or water or both by means of a hydrometer. Take the specific gravity of the radiator compound and then add water or alcohol to bring the gravity to its original value. In case you do not know the specific gravity of the original mixture you might calculate it as follows:

Specific gravity of mixture = percentage of water by weight + the percentage of alcohol by weight $\times$ .83 + the percentage of glycerine by weight $\times$ 1.27.

*See answer to D. C. Canfield's letter on preceding page.

Ford Jerks—Bands Worn

Editor THE AUTOMOBILE:—1—I have a 1914 Ford model T which always starts with a jerk, either forward or reverse. I have tried tightening up and also slacking the bands but the trouble is still present.

2—Also this motor is very difficult to start even when warm. I have ground the valves. When running it has plenty of power.

Hawthorne, Mass. H. J. PIRIE.

—1—Probably the lining on the hands is worn out. These should be relined or new bands substituted, whichever is more convenient—the cost in either case is small.

First remove the cover plate on the top of the gearbox, Fig. 4, turn the reverse adjustment and brake adjustment nut to the extreme end of the pedal shafts, and then remove the slow speed adjusting screw. Take off the upper half of the gear box. Slip the band nearest the flywheel over the first of the triple gears and turn it around so that the opening is downward. The band can now be removed without any difficulty. The operation is more easily accomplished if the three sets of triple gears are so placed that one set is about 10 degrees to the right of the center of the top.

In putting the bands back in place pass a cord around the ears of the three bands to hold them in place so that when the gearbox cover is put back no trouble will be experienced in getting the pedal shafts to rest in the notches in the band ears.

2—Adjust the carbureter to give a richer starting mixture and then if the trouble persists look for it in the ignition system.

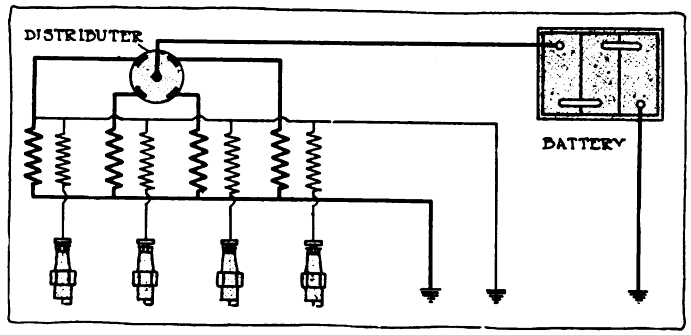

Fig. 1—Diagram showing four-unit coil system with timer, but without vibrators

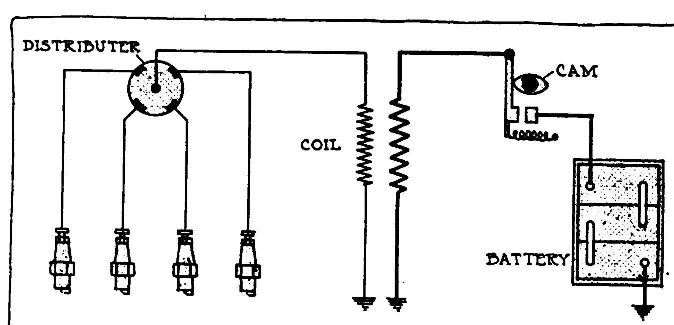

Fig. 2—System with single coil distributer and cam-actuated breaker

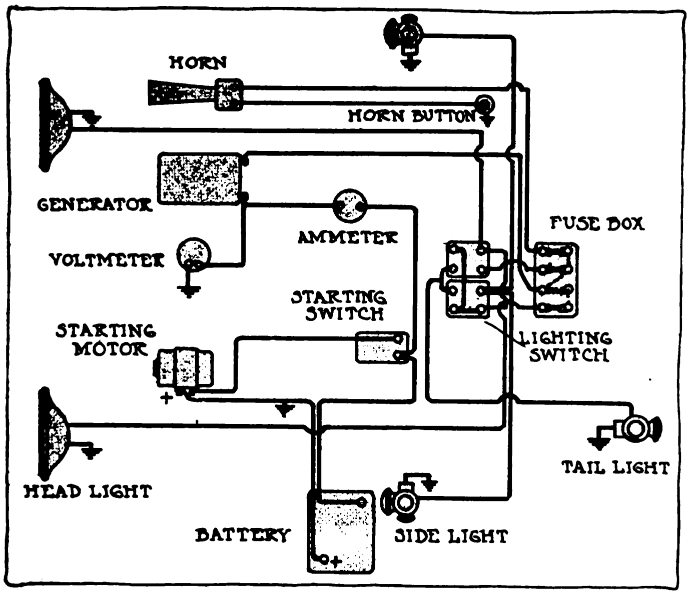

Fig. 3—Hupmobile starting and lighting wiring diagram for 1914, showing installation of ammeter and voltmeter

If the contact points are worn, dirty or out of alignment the vibrator will not work properly. The usual method of adjustment is to turn the adjusting screw up until the vibrator stops buzzing, then screw down slowly until the two points just come together and the explosion in that cylinder becomes regular. In adjusting K-W coils it is important to see that the little flat cushion spring underneath the vibrator bridge works back and forth every time the points make and break contact. This action can be determined by taking the unit out of the box and holding it up to the light; then press down the vibrator and observe the operation of the cushion spring. It is important to have all the units arcing adjusted alike. Too close contact between the adjusting screw and the vibrator will cause arcing, thus hindering the flow of the current, burning away the contact points and often putting the coil out of action. If the points become pitted or worn so that imperfect contact is made, they should be filed with a flat thin double-faced file so that the surfaces meet each other squarely.

How to Attach Electric Meters to Hupp

Editor THE AUTOMOBILE:—I have a 1914 Hupmobile with Westinghouse starting, lighting and ignition system. Would you kindly explain how a voltmeter and ammeter could be best wired from the dash to the generator?

Woodstock, Vt. E. H. REED.

—The wiring diagram is shown in Fig. 3. The voltmeter should be connected between the terminal on the generator and a ground on the motor or frame. The ammeter is connected into one of the main wires leading from the generator.

Garage for Twenty Cars

Editor THE AUTOMOBILE:—Fig. 5 shows a plan of a proposed garage on which we would like your advice.

1—How many cars do you estimate this garage would hold, considering that there will be a machine shop with a planer, lathe, drill press and gas engine?

2—Is there room to store cars lengthwise along the narrow wing of the building, and yet have room to drive by?

3—Where would be the best place for the office and accessory sales room. We do not expect to have a separate room for showing our new model cars. Both streets are main ones and have about an equal amount of motor travel.

4—In the Winter we do not have any cars running so we have the entire space for car storage. How many cars do you think it should hold in Winter?

Crestline, O. F. H. R.

—1—You can store about twenty cars according to the design shown in the figure. The exact number depends largely on the average size of the cars because different arrangements may be made according to whether the cars are large or small.

2—There should be room to store cars along this passage way, although there will be no room to spare. Two cars may be placed in the driveway as shown in the figure without causing any great amount of inconvenience. One of these cars gains entrance from the street side of the small wing and the other comes through the main garage.

3—The position of sales office and accessory store are shown in the illustration.

4—In Winter you might be able to store as many as thirty cars of medium size.

We believe that this is a very poor shape to make a garage. It is very difficult to use the space to full advantage. A more regular plot of ground would be found more satisfactory.

Medium Temperature Best for Varnish

Editor THE AUTOMOBILE:—Regarding the storing of a machine for the winter, I would like to have the following questions answered:

1—Which is the better for the paint and varnish of the machine, a cold or warm storeroom?

2—Should the tires be empty or inflated?

3—Should the tires be kept in a cold or warm place?

4—If it is advisable to put something in the cylinders (to keep the engine parts from rusting, etc), what should be put in?

5—Should anything be done with the storage battery?

Cleveland, Ohio. HENRY L. HOSSLER.

—1—A room of medium temperature is best, around 50 degrees. Temperatures above or below this figure are not particularly detrimental, however.

2—The tires should be removed from the rims, wrapped to keep out the light and laid flat. When they are stood up they deflect out of shape due to their own weight. The best atmosphere for tires is a dry one with the temperature around 50 degrees.

3—Answered above.

4—There should be enough lubricating oil from the last time the motor was operated to protect the surfaces and keep them from rusting. You need not worry about this.

5—Before storing a battery for the winter it should be put in the best possible condition, for the effects of deterioration are more or less cumulative. If it is known that a battery is in a very inefficient condition, that one or more cells are below par, that plates are sulphated, terminals corroded or jars cracked, the obvious thing is to have the conditions corrected before storage. Otherwise the battery, or at least part of it, will show considerably more than normal deterioration when again placed in active service.

Assuming that the battery is in good condition, the cells should be examined to see if they contain sufficient electrolyte to cover the plates well; if the liquid is below the depth recommended by the manufacturer the deficiency should be made up by adding distilled water or filtered rain water. Under no ordinary circumstances should acid be put in. There should be at least .25-inch of electrolyte above the plates; the depth varies slightly in different batteries.

A full charge should be given at normal charging rate, which varies according to the make and size of the battery; the charging rate almost invariably appears on the nameplate. Hydrometer tests of fully charged cells will vary a few points.

In the absence of specific instructions as to the proper density of the electrolyte, as indicated by the hydrometer at the end of a charge, it will be perfectly safe to assume that if the figures are anywhere between 1.275 and 1.300 the battery is in fairly good condition. The battery should be charged in the usual way, with slow finishing rate maintained until the hydrometer tests show no variation at half-hour intervals. If some cells read lower than others it is probable that they will continue to raise their test readings after the others have stopped rising. In such a case, continue the charge until the gravity ceases to rise in all the cells; the overcharging will not injure the cells if it is not carried beyond a few hours at a very slow rate.

Moderate Temperature Best

Batteries are best stored where there is a moderate temperature, and usually the makers recommend that they be kept where they will not be exposed to frost. At intervals a freshening charge should be given. As to whether the batteries should be removed from the car or not, the question is one for individuals to decide. If the cells can be kept clean, at moderate temperature and occasionally charged and inspected while in the car there is no objection to leaving them there. Otherwise they should be removed.

Change Every Two Weeks

As to how often freshening charges should be given, different makers give different instructions. The Willard company states "After being fully charged when put away, the battery should have a freshening charge by gravity test at least once, and preferably twice each month at the finishing rate given on the battery nameplate." The recommendations of other makers are given here.

Before the freshening charge is given, the cells should be inspected to make sure the electrolyte is above the tops of the plates. If the plates are exposed, the dry parts are liable to sulphate, while the electrolyte, made stronger by the fact that the water evaporates out while the acid does not, will have too sharp an action, and if charged and tested in this condition the hydrometer readings will be too high.

Dry Storage

Storage battery plates can in some cases be stored dry, if the trouble of charging and inspection is considered too great or if the idle period is to be very protracted—say 8 months or a year. The Gould company instructs that the battery for dry storage should first be fully charged, the cells disconnected, elements removed and positive and negative groups separated. Positive groups are allowed to dry without washing and with the acid on them. Negative groups are rinsed in water, set on a clean bench until they begin to steam, when they are sprinkled or dipped in water and again allowed to stand. They will heat and steam again, and the cooling process must be repeated, alternating with steaming, till the plates will stand without getting warm. They are then soaked for 3 or 4 hours in electrolyte of 1.275 specific gravity, dried without washing and stored. The electrolyte from the cells and the wood separators are thrown away, as they cannot again be used.

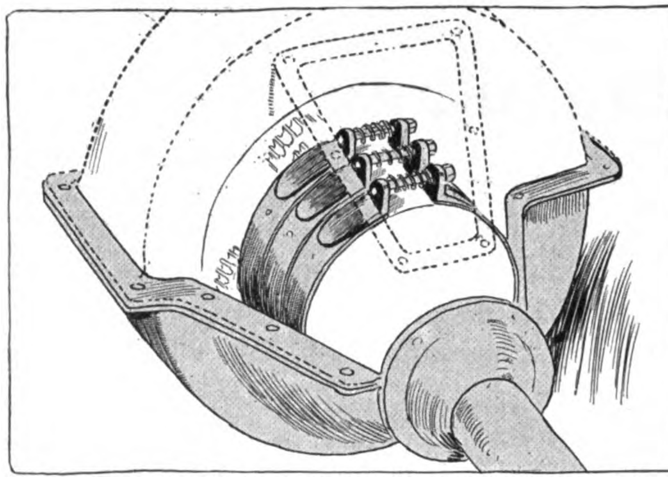

Fig. 4—Ford gearset, showing bands to be relined

The makers of the U-S-L battery state: "If the battery is drained thoroughly, washed with water and again drained carefully and then hermetically sealed, it can be stored dry for two months with every assurance of safety. The factor which would determine the length of time before the battery would commence to be injured is the drying out of the wood separators. As long as the wood separators remain moist the battery will be safe."

—One of the most important things to do, and one which you apparently have overlooked, is cleaning the car properly. If you store it the way it is, it will be very difficult to properly clean the car in the spring after the dirt has been left on the body and in the top for several months. Put the top up and brush it thoroughly, then wash it with lukewarm water and castile soap. Next clean the upholstery carefully. After this is done wash the body, first softening all mud with a gentle stream from a hose. Do not rub the mud loose by means of a sponge, if you care to perfectly preserve the body finish. After all mud and dirt have been removed, dry the surface with a soft shammy. Finally polish all metal parts and rub lubricating oil over these parts to keep them from tarnishing. The oil may be removed with warm soap and water in the spring.

Drain the water from the radiator and flush it to remove sediment.

How to Patch Celluloid

Editor THE AUTOMOBILE:—To patch a celluloid window, moisten the surfaces with acetone and press together. It holds securely and will be just as transparent as before.

Port Clinton, O. W. BUZZELL.

From Chicago to Florida

Editor THE AUTOMOBILE:—I am contemplating a trip to Florida in the next few weeks, and would like to have information as to the best route from Chicago to Jacksonville, Fla., by way of the Mammoth Cave of Kentucky.

Minooka, Ill.

GEO. O. JACOBS.

—Probably the best way according to the *Automobile Blue Book* will be through South Bend and Indianapolis. Starting from Chicago the route runs through Lafayette and Indianapolis to Louisville. From thence to the Mammoth Cave to Nashville, Chattanooga, Atlanta, Macon, Valdosta, Jacksonville, your destination.

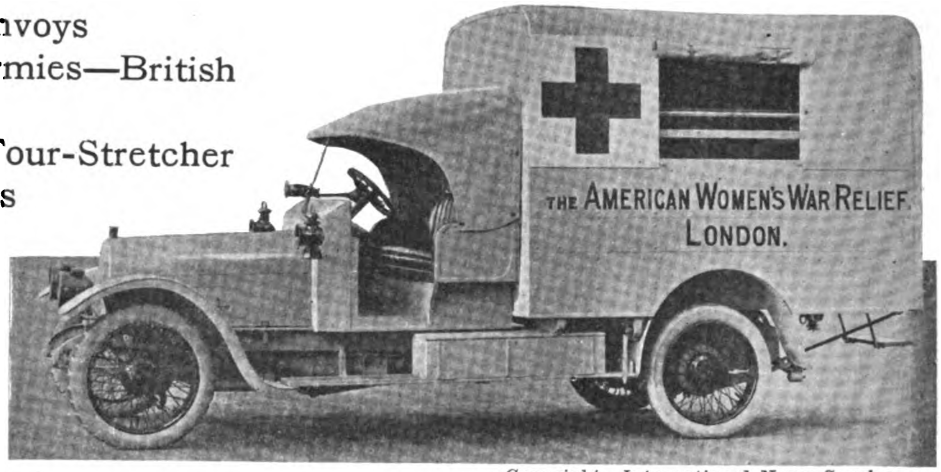
Ambulance Corps Dispatched to Front

Many Motor Convoys for Aid of Embattled Armies—British Red Cross Standardizes Two- and Four-Stretcher Body Designs



Copyright—International News Service.

One of the automobile ambulances furnished by the American Women's War Relief of London. The body, a rear view of which is given on the opposite page, is a four-stretcher design built in conformity with the specifications of the British Red Cross Society

LONDON, ENG., Dec. 1—The motor ambulance convoy for the British army in France has been dispatched to the front. It consists of forty-one ambulances, two traveling workshops, three trucks of stores, three officers' cars and ten motorcycles, and it now forms a permanent unit of the Army Service Corps. The personnel comprises five officers, eight non-commissioned officers and 136 men, all the non-commissioned officers and men being expert mechanics and good drivers. It is understood that the general design and equipment of the ambulances have been approved by Lord Kitchener. This convoy was organized by Col. Arthur du Cros, who is organizing similar corps for the Indian and Colonial Expeditionary forces. The colonel and his friends have promised to supply at least ten of the motor ambulances required.

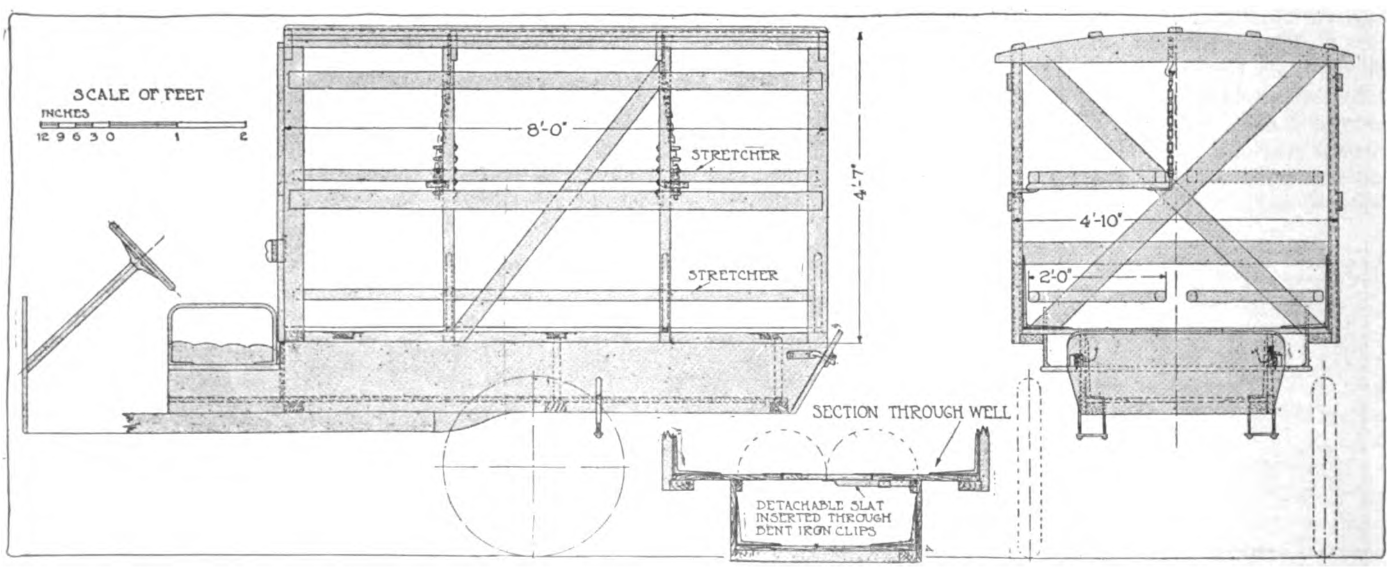
Red Cross Requirements

In this connection it is interesting to note how the British Red Cross Society is co-operating with the government and the war department in standardizing and obtaining a supply of motor ambulances.

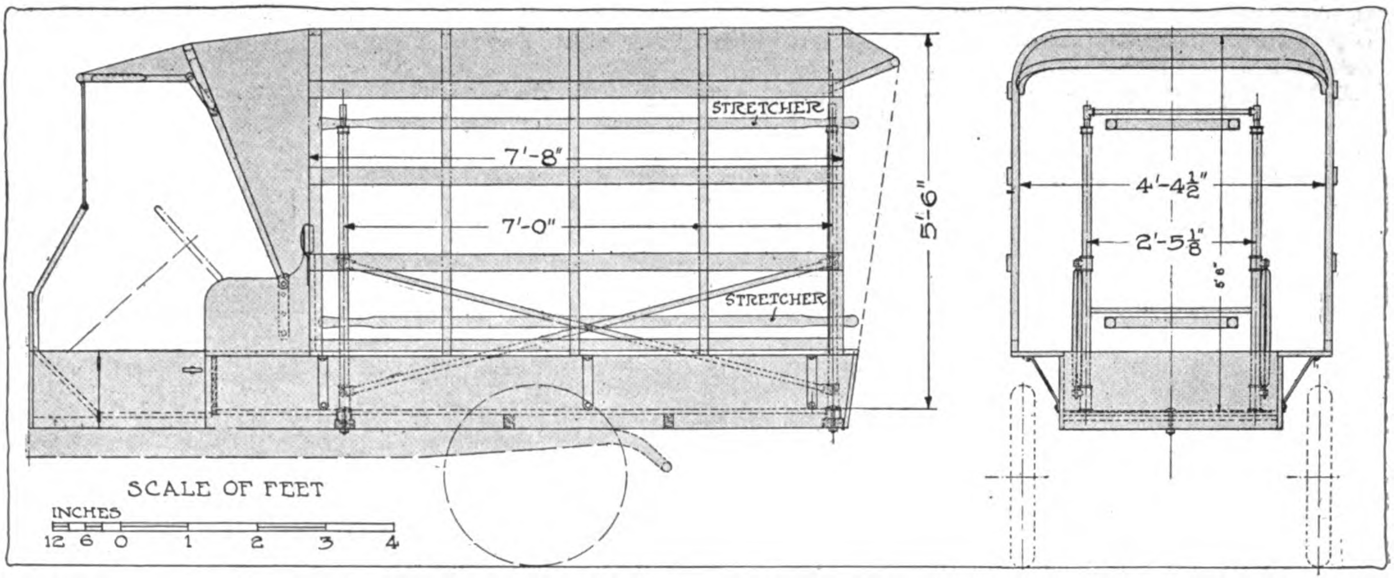
The work of the society in this is to act as a supplementary organization supporting the war department and ready at any time to meet emergency requirements which could not be anticipated, and cannot conveniently be filled by the motor ambulances owned by the government. This being the case, the problem from the point of view of the society divides itself broadly under two heads, namely, the provision of chassis and the provision of temporary ambulance bodies. The former requirement is the more numerous, because good use can be made not only of ambulances, but also of comfortably equipped touring cars for the carriage of wounded men. A very large percentage of these are able to travel in an ordinary vehicle not fitted with stretchers, and consequently, the society has expressed itself anxious to hear from car owners who would be willing to make their cars, particularly if fitted with spacious inclosed bodies, available at short notice for this sort of work.

Emergency Ambulances Needed

At the same time, a considerable number of emergency ambulances certainly ought to be provided. At ordinary times, the design of a motor ambulance, so far as the chassis is concerned, is a matter rather for the manufacturer of industrial motor vehicles than for the maker of touring cars. The speed not being particularly high, solid tires are in some cases fitted, though it is more usual to equip these machines with strong pneumatic tires of heavy section. In some instances the body is suspended on elliptical springs from the chassis, so that two distinct systems of springing are interposed between the



Working drawings of British Red Cross Society standard body for automobile ambulances of four-stretcher type with dimensions, etc.



Sketches of British Red Cross Society standard two-stretcher ambulance together with rear elevation, dimensions, etc.

patient and the road. In forming an organization hurriedly to meet requirements not exactly defined, refinements of this kind are out of the question, and probably the best course is to get the loan of well-sprung touring car chassis and to fit light and simple ambulance bodies of a type that can be constructed in a very few days. The main difficulty is in connection with the length of the chassis frame. The great majority of touring cars are not really of the right length for the work. A certain amount of space may be saved by giving the driver a somewhat narrow seat as close to the wheel as is consistent with reasonable comfort. The body itself has to be slightly over 8 feet in length to accommodate government stretchers of standard dimensions. The carriers of these stretchers are 7 feet 9 inches long, and the width of each stretcher when extended is 23 inches.

Roads a Factor

In fitting up a temporary ambulance it is necessary to take into account the fact that no one knows the nature or quality of the roads over which the vehicle may have to travel. The *pavé* roads of the Continent of Europe are calculated to cause considerable vibration in the interior even of a well-sprung pneumatic-tired vehicle, and from this vibration the patient must be protected so far as possible. Then again, very severe gradients may have to be negotiated, and consequently it would not do to overload the car.

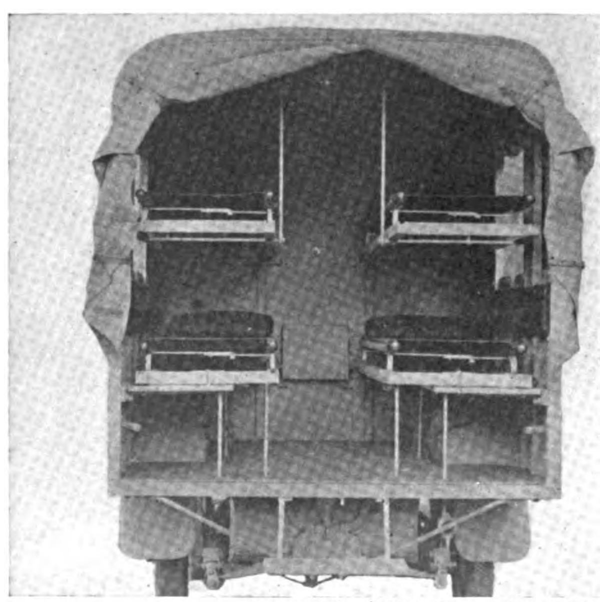
The Standard Body

In view of these and other considerations, the Red Cross Society has standardized a body of very simple construction, and consisting of a light framework covered with waterproof canvas, and having canvas curtains at the front and back. The floor of the body has to be fairly substantial, and provided with two transverse grooves to take the base of a suitable equipment designed to carry stretchers. The equipment selected is of the type known as the L.X.R. It consists essentially of a braced framework of steel tubes. The four upright corner tubes are slotted to take the ball ends of steel cross bars from which the stretchers are suspended. The cross bars when slipped into position do not bear upon rigid metal, but upon the tops of strong coiled springs contained in the corner tubes of the structure. Each equipment takes two standard stretchers with ample head and air room between and above them.

It will be noted that the whole arrangement provides what is tantamount to a second system of spring suspension between the patient and the road surface, and this without suspending the stretchers loosely or in any such way as to allow of any rolling or pitching relative to the movement of the vehicle itself. It has been found that if stretchers are loosely slung from above so as to be free to move to some extent, a periodic rolling motion is set up while the vehicle is traveling, and this not only gives to the patient a sense of insecurity and danger, but has a physical effect akin to that of the rolling of a ship at sea. It is, consequently, very necessary for the stretchers to be carried from the cross bars by short ropes, making them for the time being into one rigid structure with the bars from which they are borne.

A Four-Stretcher Type

Some use under certain conditions is also likely to be made of vehicles built to another design, in which the stretchers are not in any way sprung from the body, but the body itself is more stoutly constructed and is of larger dimensions. This second arrangement gives accommodation for four stretchers, two of which rest on the floor, while the other two are carried on supports slung by chains or ropes from the roof. The system should be satisfactory enough at low speeds over fairly good road surfaces, and one advantage of the arrangement is that the body can conveniently be constructed with a well,



Copyright—International News Service.

Rear view of American Women's War Relief four-stretcher automobile ambulance illustrated on the opposite page, showing arrangement of stretchers the floorboards of which can be hinged back. The idea of this is that when a number of men who are able to travel without stretchers have to be carried, the well can be opened and the vehicle is then turned into a sort of rough wagonette with seating accommodation along either side. This makes it possible to carry about twelve men at a time, or alternatively, to carry a couple of stretchers on one side of the well, and half-a-dozen men sitting on the other side.

So far as the chassis are concerned, the British Red Cross Society has to depend on the generosity and patriotism of motorists who are asked to lend their cars, and, if possible, their own or their chauffeurs' services for driving, without any charge. It is an easy matter to get offers from motorists to carry out specific jobs for the government or any accredited society like the Red Cross. It is, however, far less easy to persuade them to allow their cars to be made useless for ordinary purposes for a considerable length of time on the chance of their being needed sooner or later for urgent ambulance work. At a time when everyone feels that he would would like to be doing something useful, it is very difficult to get people to realize that the most useful thing to do may quite possibly be to sit down and wait patiently until one's services are needed.

A Matter of Short Notice

It is not, of course, possible even to state with certainty whether the military authorities will need any help on a considerable scale from the British Red Cross Society as regards the supply of motor ambulances. On the other hand, it is likely enough that if such help is wanted, it will be wanted at short notice. Consequently, it is not enough to have cars ready to be converted when required; the conversion ought to be carried out beforehand, and the cars should be standing in some convenient garage available to be sent out to any point where they may be needed at a very few hours' notice. A considerable number of British motorists have offered themselves and their cars for ambulance service either at home or upon the Continent, but, as is indicated above, the main difficulty in the way of perfecting the whole organization is the uncertainty as to what will be required, and the extent to which the Red Cross Society will in fact be called into cooperation by the government.

To Mill 250 Continental Motor Cylinders in 10 Hours

¶ *"A 42-centimeter gun in the motor building business," is what an official calls the new 40-foot milling machine recently installed at the Detroit plant of the Continental Motor Mfg. Co. This is said to be the largest device of its kind ever built and set up in any motor plant in the world. The weight is 42,800 pounds.*

¶ *In order to get the machine into place, it was first necessary to tear down a section of the solid east wall of the large Continental machine room. The highest production possible will be obtained when this great milling machine is finally ready for work, with its special loader and its complete equipment of eight fixtures. It has been estimated that a new record of 250 milled cylinders in 10 hours will be set when the giant gets to grinding away.*

A Field for 750,000 Trucks

Figures Based on Horse Population in United States of 25,000,000—30,000 Users Have 70,000 Trucks Worth $140,000,000—329 Firms Building Commercial Vehicles

NEW YORK CITY, Dec. 16—"Seven hundred and fifty thousand motor trucks carrying an average load of 2 tons each would be needed to handle the freight of 2,000,000,000 tons carried each 12 months by our railroads, this allowing for 300 working days per year, and handling this freight at both ends of the line." In these words Horace M. Swetland, president of the Class Journal Co., and a pioneer in the automobile publication field as well as a critical student of automobiling, summed up the future possibility of the motor truck industry at the annual meeting of the Motor Truck Club of America held in this city tonight. Mr. Swetland in a measure verified this estimate by a consideration of the annual stock yards' report which shows that approximately 25,000,000 horses and mules are employed in this country for all purposes, and if one-tenth of these are employed solely in trucking work and assuming that the motor truck will do as much work as three horses, this brings the same conclusion, namely, that 750,000 trucks would be needed if all horses were supplanted.

8 Years' Progress

In his opening address Mr. Swetland referred to an address made 8 years ago before a national team-owners' convention at which his remarks on the future of the motor truck were received with ridicule by the team-owners present. "Today," continued Mr. Swetland, "I might further inform you, that 30,000 users have 70,000 motor trucks, an average of 2 1-2 trucks per user, representing an investment in vehicles alone of $140,000,000; that 329 different motor truck makers are attempting to supply the demand for these vehicles; and that the daily consumption in labor and supplies for operation of these 70,000 motor trucks and delivery wagons is $560,000; and that this expenditure produces a daily transportation of practically 1,500,000 tons of freight. To this great industry which has grown up in the past 8 years must be added the hundreds of passenger vehicles used solely in this service. Today 30,000 individual firms have adopted motor trucks.

"But this great development could not be inaugurated without many failures, without much reconstruction, without the adoption of new methods involving the regulation of street traffic, the betterment of roads, and a thorough reorganization of the system of handling tons of freight and thousands of passengers. And, so, for many years the struggle against inefficient conditions, inefficient machines and inefficient operation has gone forward until today we are positive that the machine is cheaper than the horse for any continuous and regular service.

"Perhaps road-making has been the greatest essential to the success of this modern development, and it is true that it is possible to wade a horse through a mire hole and have him drag a few pounds after him where it would be impossible to operate a motor-driven vehicle, but the mire hole is being eliminated, and solid macadam and substantial paving have already proved essentials to both horses and machines. It naturally follows that the development of this great industry has followed the improvement of city highways and suburban roads. In the State of Massachusetts, which was among the first to preach the doctrine and demonstrate the serviceability of good roads, and which has ever lived up to its ideals in this particular, the registrations of truck sales show an increase of 40 per cent. in 1914 over 1913, and wherever the improved highway has blazed the trail sufficiently plain, the motor truck has followed and followed successfully.

Early Selling Methods

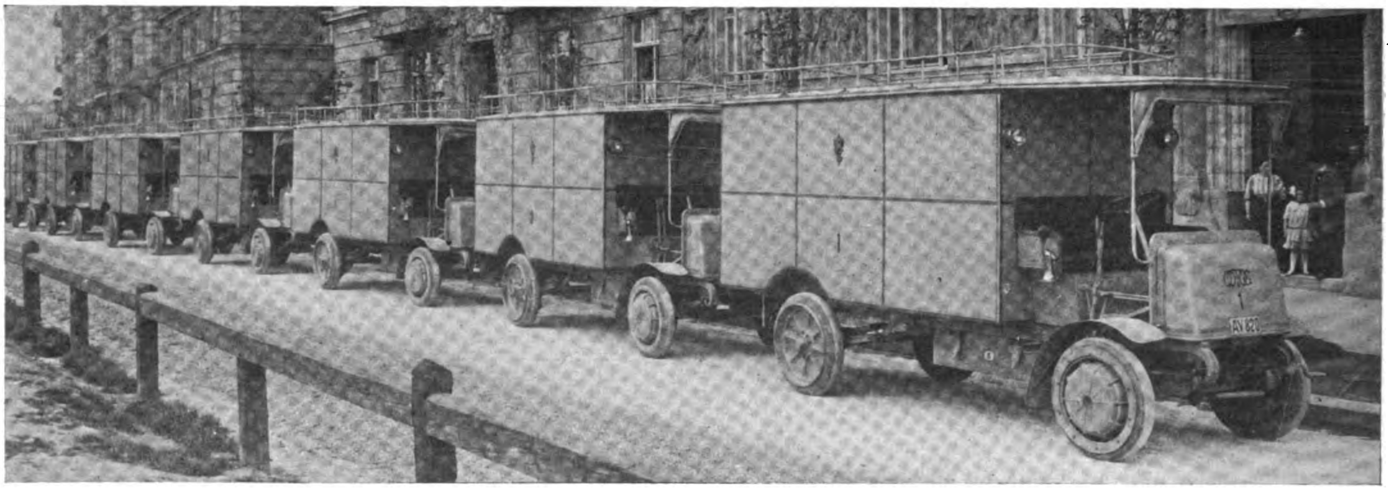
"When the salesman first started to sell trucks, he sold them on the same basis that pleasure cars had been sold, that is, on any kind of a basis to get the sale and get the money. All sorts of extravagant claims were put forth by the salesman, absolutely ridiculous and unheard of guarantees were inserted into contracts, and the over-ambitious salesman did as much to block the progress of this industry as any other single contribution. He was strongly backed up by the manufacturer, who inherited from the pleasure car business the old idea that the people would buy anything that had four wheels under it, and looked like the real thing, was foisted on an innocent and ignorant constituency. Then the owner added the last straw to the camel's back, and while he purchased a 1-ton truck which the salesman had suavely assured him would carry 2 or 3, he had simply looked at the luggage space, smiled up his sleeve and said, 'I can easily put 4 tons of my material into this wagon-box,' with the result that the unfortunate machine, however well it may have been designed, and however faithfully it may have performed its 1-ton truck service, was wholly insufficient for two or three times that amount.

"The machine was not only overloaded but was placed in wholly incompetent hands, and the man who had given the lash of the whip to the horse, applied the same method to the truck, and finding the beast inanimate and insensible of his threats and his whip, had adopted the only other method which could reach its vitals, that is, that of starvation, inattention and over-driving.

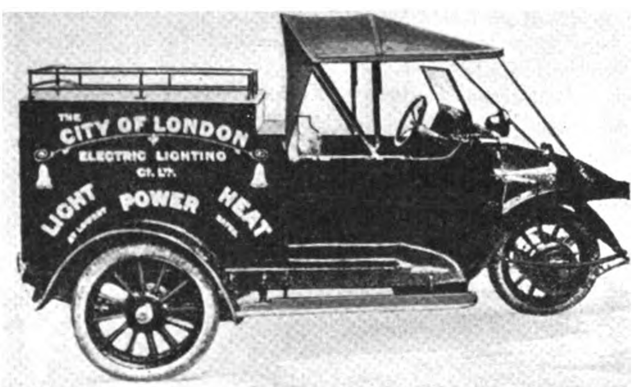
A Broader Education

"If all the educational matter which is handed to us through the various institutions of learning were confined to the individual efforts of a single intelligence, our education would probably begin with the table of addition, and end in long division. The mass of educational facilities which are at our disposal today is the result of the broadest individual experience and investigation, combined with the facilities for the interchange of the information thus obtained. In this we are able to take advantage of the experience of others, and while we may individually contribute our mite to this mass of information, it is the possibility of knowing what everybody else knows that multiplies our educational advantage. Therefore, any organization which has for its object the assimilation and distribution of facts pertaining to a thing common with the experience of others in the same line, not only becomes a powerful factor for individual advantage, but raises the whole standard of educational opportunity to a plane of the highest efficiency. It is when your experience in eliminating the waste time and delay consequent to loading and unloading, can be exchanged for the experience of another relative to the development of motor efficiency, and when this can be exchanged with all others who have made careful study and experiment along other lines, that the greatest results can be attained."

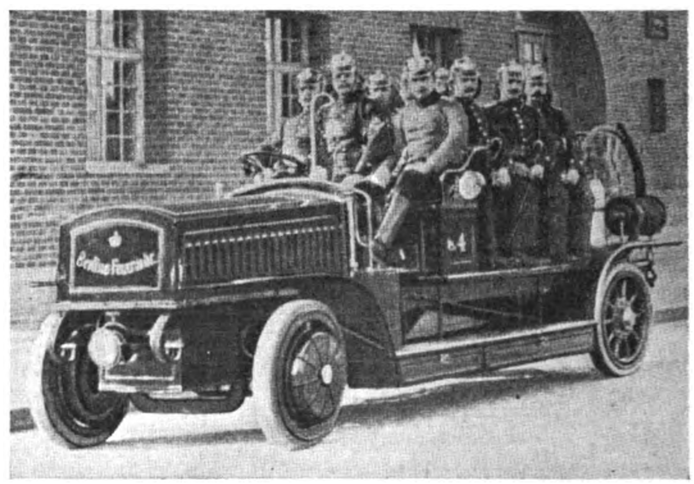
How Electrics Are Used Abroad



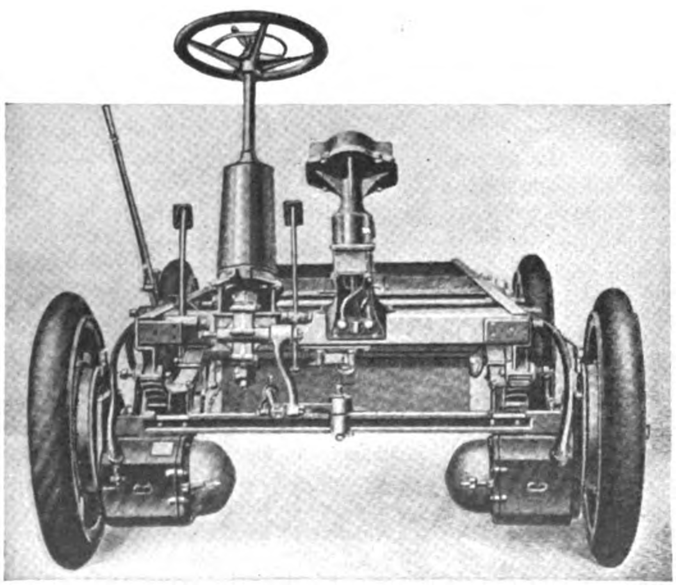
Part of the fleet of thirty 2.5-ton Electro-Daimler wagons put into mail service in Vienna. Chassis were constructed by the Austrian Daimler company. The bodies are of special design and are built by the Imperial Wagon Works, of Austria. Wheelbase of the machines is 130 inches. Two-motor, front wheel drive is used, the two motors giving a maximum of 15 horsepower at 90 volts. Batteries are of the forty-two cell lead type and are rated at 300 ampere hours, giving a mileage of 43.4. Each battery weighs 1,918 pounds



Three-wheeled Torpedo electric, with van body, used in London. The driver is protected by the top and windshield



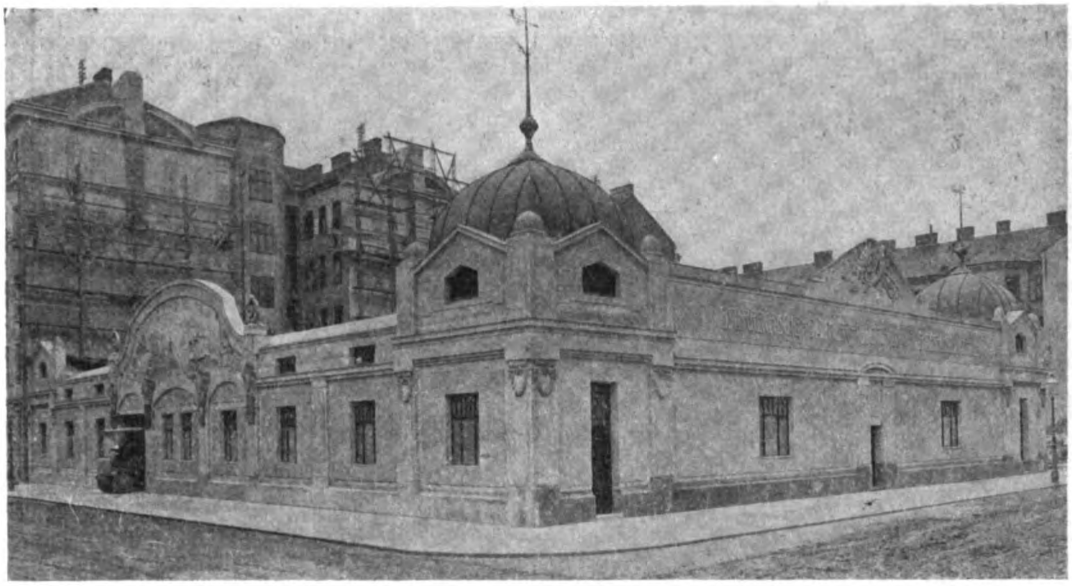
The Berlin Fire Brigade was using twenty-four electrically-driven vehicles in March of this year. The type illustrated above is one of the powerful machines designed for carrying hose, chemicals, etc., besides a crew of firemen. Note motors for driving front wheels and brakes on front wheels



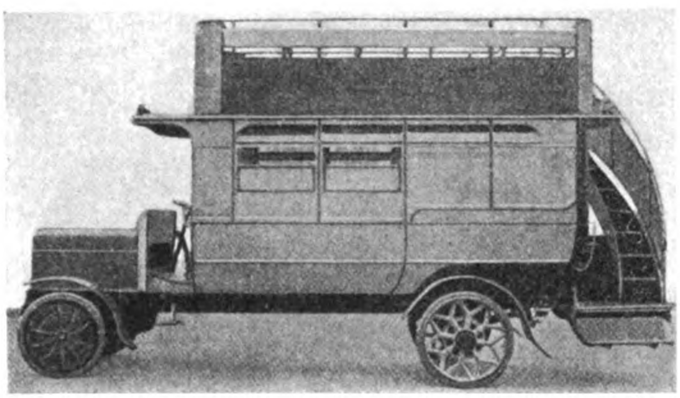
Chassis of Namag electric made in Germany. Note motors for driving front wheels. Also front wheel brakes. The type of control is similar to that employed on gasoline-driven cars

F.R.A.M. 4-ton garbage cart with steel body used in Paris. These trucks weigh about 9 tons and have a speed of 8 miles per hour. The chassis are De Dion-Bouton-Fram products. Batteries are lead and weigh 1 ton each

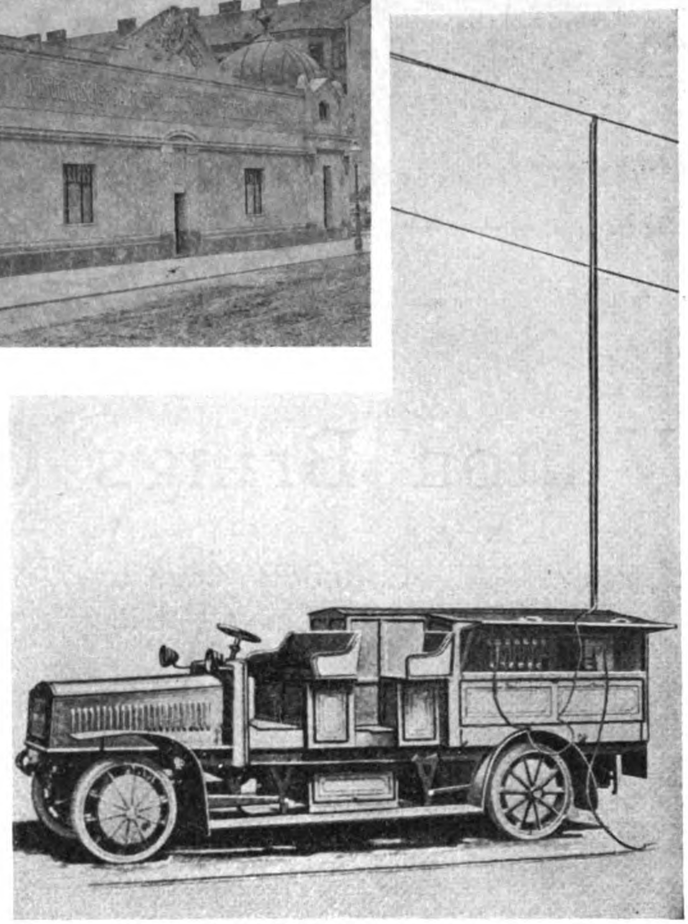
Illustrations and data appearing on these pages are from the paper of P. D. Wagoner, entitled European Development of the Electric Vehicle Industry, read at the Convention of the Electric Vehicle Assn. of America in Philadelphia, October 19-21



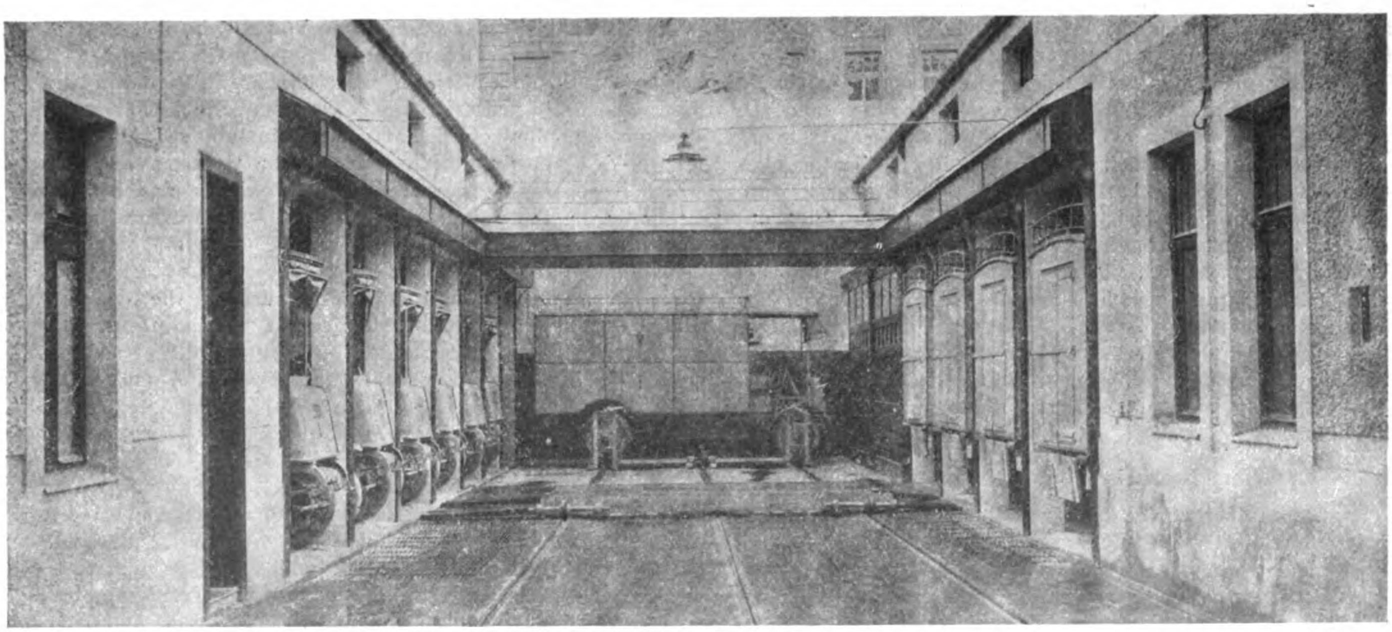
Where the electric mail vans are garaged in Vienna. The building is 131 by 102 feet, of one story and basement, and fronts on three streets. The interior, together with the idea of stalls for the cars, is illustrated below



Cedes gearless electric bus with latest type of London body. **There are only a few score electric buses in existence in the various European countries and fleets made up of vehicles of this type are unknown there**



The 3-ton electric used by the Great Berlin Tramways for repair work. It may be charged from the trolley, as illustrated



Interior view of garage for electric mail wagons in Vienna, showing stalls for the cars, turntable mounted on rails for shunting them to any desired aisle, etc. By an ingenious arrangement, batteries are brought up directly under the vehicles as on an hydraulic lift

Winton Brings Out Smaller Six

Cylinders 3.625 by 5.25 Inches—Spiral Bevel Axle Drive—Electric Starting and Lighting

WINTON has announced another model in addition to model 21. It is known as model 21-A and is a smaller six than the Winton of the past few seasons. While in general design the new car is similar to the larger model which is continued, there are many changes in dimensions throughout giving a lighter vehicle in all particulars.

Model 21, the present Winton, has a 4.5 by 5.5-inch motor, but the new 21-A is 3.625 by 5.25. The S. A. E. rating of model 21 is 48.6 and that of the new car 31.6. The larger Winton sells for $3,250 and the new one for $2,285 with a five-passenger body and full equipment. The new car is 2 inches shorter than its running mate, having a wheelbase of 128 inches. The tires are also smaller, being 36 by 4.5 whereas the larger car uses the 37 by 5 size

The power plant has six L-head cylinders with valves on the left. The valve action is completely inclosed and the crankcase is extended back to include the flywheel. This is a difference in design which is noticeable in the Winton 21-A as in model 21, the flywheel is exposed. The valves are operated from a single camshaft with integral cams. The camshaft is removable through the front end of the crankcase without altering the valve adjustment and is driven by steel spiral gears completely inclosed in an oil-tight housing. The valves are interchangeable in size, but are tungsten steel for the exhaust and carbon steel with nickel-steel heads for intake. The valve springs, plungers and adjustment nuts are covered by steel plates which are detachable by removing hand screws.

Chrome-Vanadium Crankshaft

The crankshaft is of chrome-vanadium steel having a tensile strength of 125,000 pounds to the square inch. It is carried on four plain bearings lined with Parsons white brass. All the bearings are contained in the upper half of the crankcase.

As will be noted from the illustration showing the right side of the motor the carbureter is carried quite high and is bolted by means of a short elbow against a balanced intake manifold. This new model has the carbureter and magneto on the same side. In the model 21 the carbureter is on the left and the magneto on the right. The installation of the magneto, water pump and generator is along the same horizontal shaft on the right. The mountings for the pump and the two generating instruments, the magneto and generator, are secured by bases built up on a horizontal crankcase flange. The air pump is carried at the forward end of the crankcase on the right side; but, instead of being a four-cylinder model, as in the larger six, is a single cylinder.

Lubrication is by a pressure-feed system in which the oil is circulated by a gear pump located in the crankcase. This pump takes its drive by spiral gears from the camshaft and delivers oil through a lead in the crankcase to the main bearings, whence it passes to the lower connecting-rod bearings through the hollow crankshaft. An adjustable overflow valve is provided allowing oil to pass to the timing gears after which it returns by gravity to the crankcase and is again circulated by the pump. This gives a pure pressure system with the exception that the cylinders, cams and camshaft bearings are fed by the oil which is thrown by centrifugal force off the cranks. Oil grooves are used in the pistons to distribute the oil over the surfaces of the cylinders. The quantity of oil fed is regulated by a bypass. As the motor speeds up less oil is fed through the bypass and more to the motor.

Bosch Dual Ignition

Ignition is by Bosch magneto with battery to supply auxiliary current for starting. The magneto is connected to the driveshaft by an adjustable Oldham coupling placed between the magneto and the water pump. The balance of the electric equipment for lighting and starting is made up of the Bijur two-unit system.

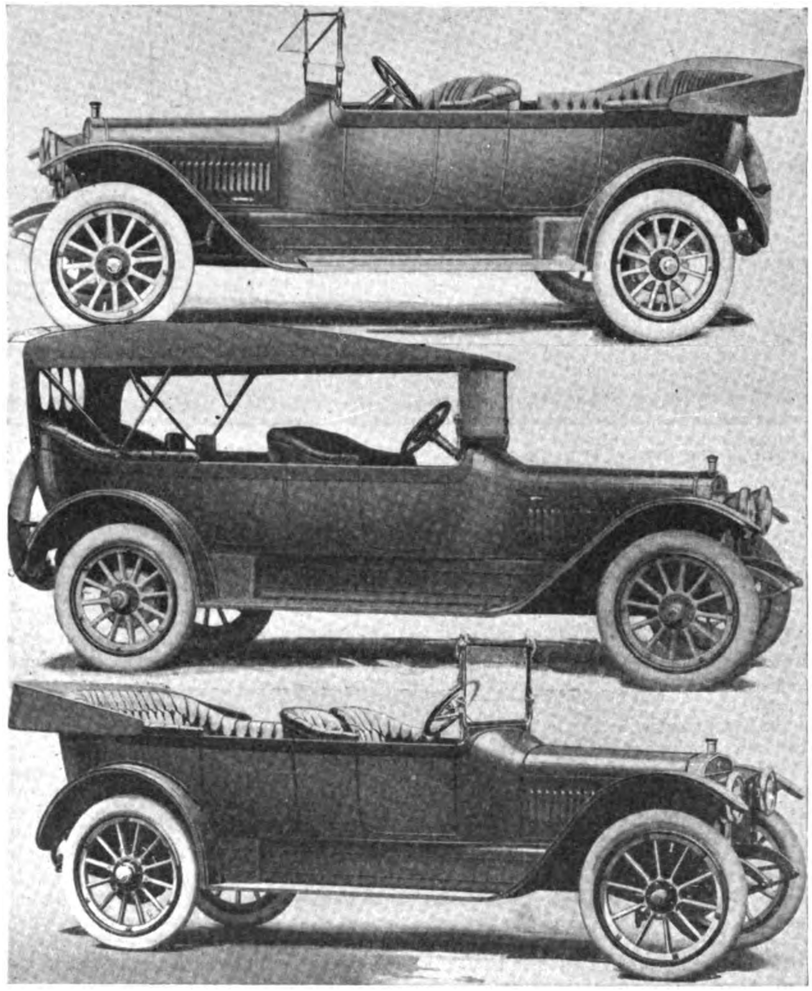
The cooling water is circulated by gear-driven centrifugal pump. To keep the water pure and to prevent corrosion each surface is plated with an anti-rust coating. The radiator is a honeycomb bolted to the drop frame. The tension on the fan belt is adjustable by a slotted bracket.

The dry-plate disk clutch has eleven disks in all, six attached to the driven shaft and five keyed to the drums driven by the flywheel and the clutch can be removed and replaced without interfering with either the gearbox or the crankcase. Power is transmitted by means of a four-speed selective gearbox with direct drive on third speed and with fourth speed geared above direct. The driveshaft is designed to be practically horizontal under normal load and has a universal joint at each end. The floating rear axle uses a pressed steel housing. The axle shafts, differential gears and bearings may be removed without lifting the wheels from the ground. The differential is a bevel design but the drive from the driveshaft to the large gear wheel is by spiral bevel. The gears and pinions are of nickel steel and throughout the entire rear system is carried upon Timken roller bearings.

Elliott Front Axle

The front axle is an Elliott type drop forging of I-beam section with practically horizontal connection between the steering gear and the left front wheel. Worm and gear mechanism is used to transmit the steering moment from the 18-inch steering wheel. Self-lubricating bushings are provided on the steering column and the steering links are adjustable. The steering arm is over the front axle and two yokes and two adjustable ball joints are provided.

A low center of gravity is secured by a pronounced drop in the frame just forward of the rear axle. The frame is narrowed forward and is constructed without a subframe. Either wood or wire wheels are offered as an option to the purchaser. The Firestone tires are non-skid in the rear as regular equipment.



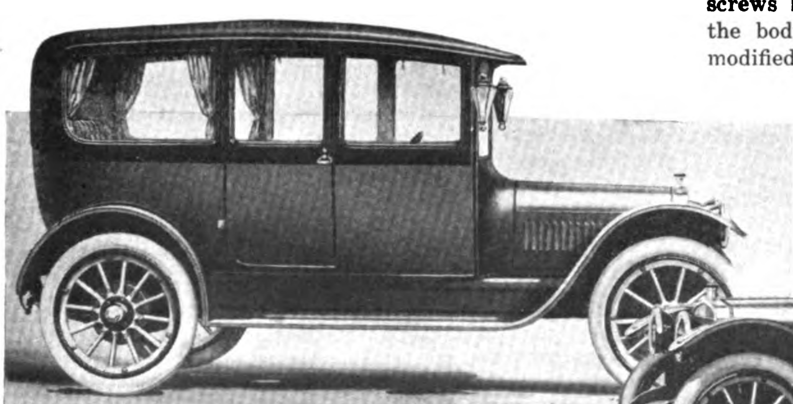
Upper—Five-passenger touring car mounted on Winton larger six-cylinder chassis and selling for $3,250
Middle—Seven-passenger type on same chassis as above. It lists at $3,500. Note stream lines and spare tire at rear
Lower—The new smaller six model Winton fitted with a five-passenger body and selling for $2,285

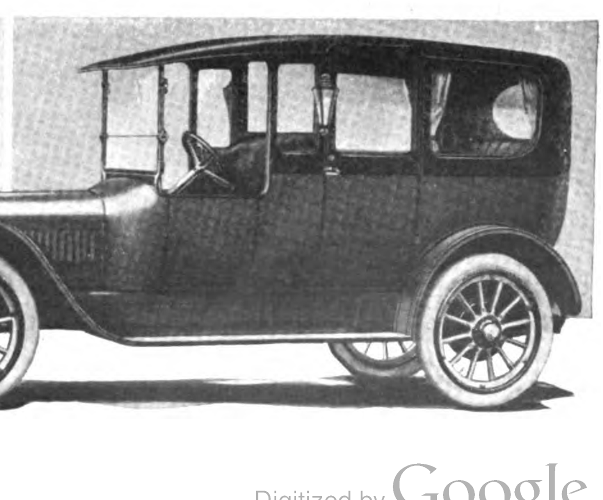
Five gear reductions are offered as optional. These are 4 1-12, 3 10-13, 3 1-2, 3 4-15 and 3 1-16 to 1. The following table shows the speed of the car in miles per hour on each of the four speeds for three of these reductions:

Final reduction	4 1-12 to 1	3 10-13 to 1	3 1-2 to 1
First speed	7.8	8.4	9.1
Second speed	16.0	17.2	18.6
Third speed	25.5	27.6	29.8
Fourth speed	32.4	35.0	37.8

Left drive and center control are used. The horn button is in the center of the steering column. The clutch and brake pedals are adjustable for length.

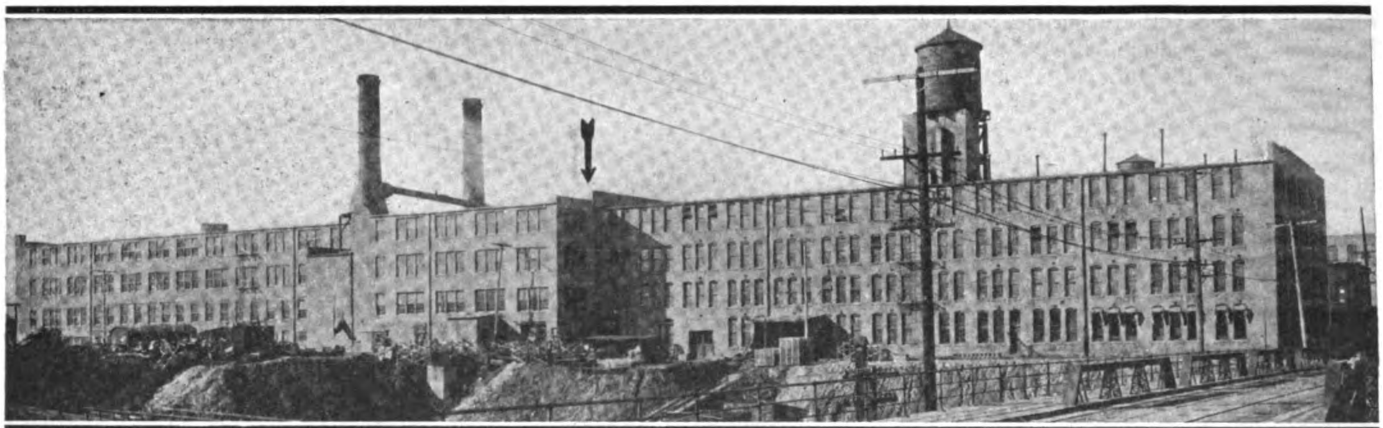
All the instruments are carried on the cowl board and include the lighting switches, ammeter, carbureter control, primer, speedometer, clock and ignition switches. Over the cowl board is a ventilating, rain-vision windshield. There are no side lights, but dimming lights are carried in the head lamp. All the wires are inclosed in flexible tubing and the wires running from the chassis to the body terminate on a terminal strip secured to the lower side of the fusebox, located on the engine side of the dash. The removal of two screws breaks all connection between the chassis wires and the body. The distinctive Winton body lines are slightly modified to conform with streamline practice.





Above—Sedan body mounted on the smaller Winton chassis and selling for $3,500

Right—Three-quarter limousine on new chassis, $3,250



Plant of the Racine Mfg. Co., Racine, Wis., the portion to the left of the arrow being the large addition made this year. The additional floor space amounts to 200,000 square feet. Cost of additions was $75,000

Car, Truck and Accessory Plants Expand

(*Continued from page* 1153)

Atlas Drop Forging Co., Lansing, Mich., has occupied an entire new factory of five buildings comprising 50,000 square feet of floorspace at a cost of $150,000. About $45,000 was expended for new machines.

The Allegheny Steel Co., Pittsburgh, Pa., has expended $161,894 for new machinery and equipment.

Allen Auto Equipment Co., New York City. Machinery, $1,000.

A warehouse and stockroom added to the plant of the American Die & Tool Co., Reading, Pa., increasing its floorspace 2,500 square feet. Machinery, $10,000.

A complete new factory has been occupied by the American Ever Ready Works, Long Island City, N. Y. The new factory has eight floors each 200 by 300 feet and represents an expenditure of $1,000,000.

The new factory of the Ashland Mfg. Co., Ashland, O., comprises two buildings, one 50 by 150 and the other 55 by 100 feet. Both are two story frame structures. The company suffered loss to the extent of $1,200. Machinery, $3,500.

The Atlas Crucible Steel Co., Dunkirk, N. Y., lost $50 by fire during the year. Machinery, $5,000.

A new factory has been occupied by the Automatic Transportation Co., Buffalo, N. Y., two stories in height and 53 by 150 feet and a machine shop of 15,000 square feet has been added at a cost of $40,000. Machinery, $10,000.

The Automobile Hospital Co., Cleveland, O., has moved to a new location, a two-story building 30 by 90 being occupied. New machinery worth $1,000 was installed.

The Automobile Supply Mfg. Co., Brooklyn, N. Y., has expended $31,000 on new machinery.

The Auto Parts Co., Providence, R. I., has added a new assembly and office building of 12,000 square feet of floorspace at a cost of $25,000.

The Barth Mfg. Co., Milwaukee, Wis., has spent $500 for new machinery.

An increase of 100 per cent. in floorspace has been made by the Bijur Motor Lighting Co., Hoboken, N. J., representing 50,000 square feet. Machinery, $100,000.

The Breeze Carbureter Co., Newark, N. J., has added about 120 square feet at a cost of $1,500. Machines, $2,800.

The Brown Co., Syracuse, N. Y., is occupying a new two-story and basement factory 175 by 60 feet, has $5,000 on new machinery and is adding more.

The Brown-Lipe-Chapin Co., Syracuse, N. Y., has expended $60,000 on new machinery.

The Central Brass & Fixture Co., Springfield, O., has increased its manufacturing space 4,000 square feet at a cost of $1,000. Machinery, $500.

A four-story addition comprising 45,000 square feet has been made by the Champion Spark Plug Co., Toledo, O. The addition cost $60,000. Machines, $100,000.

By the purchase of adjoining factory the George P. Clark Co., Windsor Locks, Conn., has added 11,000 square feet to its floor space and added machine equipment worth $6,000.

Large additions have been made by the Continental Motor Mfg. Co., Detroit, Mich., comprising a machine-shop, test room, hardening plant, stamping dept., stockroom and garage, totaling $75,000 square feet. The additions cost $50,000. Machinery $150,000.

The Davis Mfg. Co., Milwaukee, Wis., is now building a new plant 290 by 250 feet.

About $500 has been invested by the Dayton Body Co., Dayton, O., for new machines.

Dayton Rubber Mfg. Co., Dayton, O., has added new machinery worth $25,000.

The Detroit Gear Machine Co., Detroit, Mich., has added 10,000 square feet of floorspace at a cost of $17,000. Up to November 1, the company spent $16,000 for new machinery.

Detroit Leather Works, Detroit, Mich., spent $600 for new machines.

Diamond Chain Mfg. Co., Indianapolis, Ind., added machinery worth $100,000 during the year.

Two additions totaling $10,000 square feet were added by Edmunds & Jones Mfg. Co., Detroit, Mich., at a cost of $25,000. The company has partially occupied a new factory, one building being 35 by 120 and one 50 by 125 feet. Machinery, $7,500.

Essex Storage Battery & Supply Co., Newark, N. J., has added 1,100 square feet at a cost of $2,800. Equipment, $2,800.

The Esterline Co., Indianapolis, Ind., has purchased machinery worth $3,500.

A finished stockroom of 4,800 feet has been added by the Falls Machine Co., Sheboygan Falls, Mich.

The Federal Rubber Mfg. Co., Cudahy, Wis., near Milwaukee, gave orders for new factory buildings to cost over $500,000 in July. When completed, these additions will mean an increase of 150,000 square feet, making the total floorspace of the company 450,000.

Fuller & Sons Mfg. Co., Kalamazoo, Mich., have spent $1,000 for new machinery.

G. & A. Carbureter Co., New York City, has spent $1,800 for new machinery.

A large wing of 1,500 square feet has been added by the Garage Equipment Mfg. Co., Milwaukee, Wis., to provide more office, storage and manufacturing space at a cost of $5,000. Machinery, $10,000.

Quarters containing 2,000 square feet of floorspace have been rented by the Gleason-Peters Air Pump Co., Brooklyn, N. Y. Machinery, $1,500.

New machinery worth $400,000 has been added by the Goodyear Tire Co., Akron, O.

Gray & Davis, Inc., Boston, Mass., expended $120,000 on additional machine equipment for its new factory.

The Emil Grossman Mfg. Co., Brooklyn, N. Y., has invested $5,000 in new equipment.

About $5,000 has been expended by the Guide Motor Lamp Mfg. Co., Cleveland, O., on new machinery.

A third story has been added by the Gurney Ball Bearing Co., Jamestown, New York. The additional space thus obtained is 6,000 square feet at an expense of about $10,000.

A two-story addition 150 by 50 feet containing 7,500 square feet of floorspace has been made by the L. P. Halladay Co., Streator, Ill., $12,000. New machinery, $10,000.

Haynes Mfg. Co., Detroit, Mich., has spent $10,000 on machinery.

Heissler Storage Battery Co., Chicago, Ill., is occupying a new factory, 25,000 square feet, an increase of 10,000. The investment represents $30,000 to $50,000. Machinery, $15,000.

An investment of $5,600 has been made by the Hess-Spring and Axle Co., Carthage, O.

The Hilliard Clutch & Machinery Co., Elmira, N. Y., has added $500 worth of new machinery.

Left—Exterior of new Stromberg, known as the KO. Right—Section showing balanced valve construction

Balanced Valve On New Stromberg

Takes Place of Auxiliary Air Valve—Only One Nozzle and One Air Opening

A NEW carbureter which differs radically from former Stromberg designs in that the auxiliary air valve is displaced by a balanced valve has just been announced. The new instrument has one nozzle and one air inlet.

The features of the new Stromberg, are the balanced air valve, which if its action were not known, would be referred to as an auxiliary air valve, and the method of using the air, which is taken through this valve in such a way as to give, with a single nozzle, the gasoline flow previously obtained with separate low speed and high-speed nozzles. Briefly, the balanced valve in operation diverts a portion of the air flow taken through the main inlet and this diverted air passes through the carbureter body to a point at the upper end of the venturi tube. The air passage at this point is formed like the entrance of a larger venturi tube and acts in such a way as to cause the air which has entered through the balanced valve to exert additional suction in the primary venturi tube. This additional suction and the added gasoline feed are in proportion to the auxiliary air admitted, so that while there is only one nozzle and one air inlet there are really two air currents exerting a compound action on the gasoline jet.

There is a small passage P which connects the chamber B with C. The chamber A above the piston always contains air under atmospheric pressure except when the dash control valve or air intake shutter is used, because of its communication with the chamber D through the space around the spring and up through the sleeve of the valve.

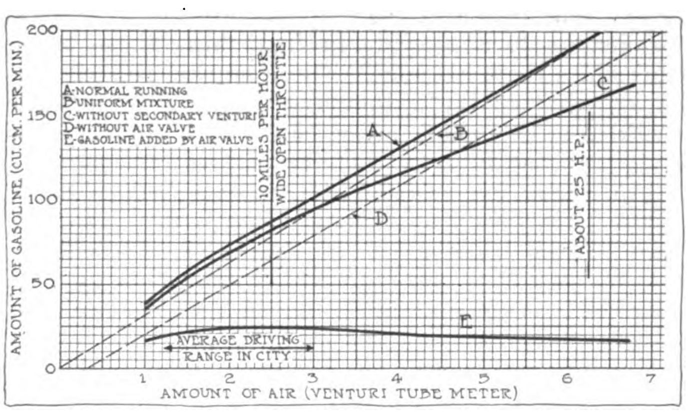
The vacuum B is substantially the same as that in C which is, of course, determined by the demand of the motor and the strength of the air valve spring. A light spring is used so that this vacuum is always very small, perhaps 8 ounces. As a result the air valve tends to move upward by difference in pressure between C and D, while the piston tends to move downward by the difference in pressure between A and B. As the piston is approximately twice the area of the valve, the whole valve opens downward but the balance between the chambers is such that the pulsations of motor suction are deadened and the valve flutter thus eliminated.

When the carbureter is in action and the engine running idle, the valve is slightly off its seat. The single nozzle feeds the gasoline and the primary venturi supplies nearly all the air. As the engine speed is increased or the throttle opened, a greater demand is made on the air valve, which opens, admitting additional air. When this air reaches the top of the venturi it increases the suction in the venturi and draws additional fuel, so that the supply taken is in proportion to the amount of air which passed through the valve. In other words, as the air valve opens there is an increase in the supply of gasoline as well as the air sent to the motor, thus the result obtained is like that given by a carbureter with two fuel nozzles and two air inlets.

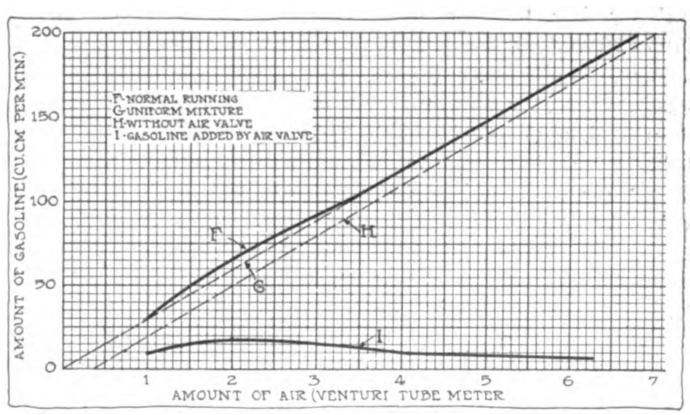
The balanced valve does not flutter, but operates gradually as the pressures vary. At low engine speeds the position of the valve regulates the mixture, but above 25 miles an hour, according to the Stromberg engineers, the valve may be opened all the way without noticeably affecting the running of the engine except to admit a slightly greater charge.

In practice all hot air is used, taken from a tube connecting with a housing surrounding a portion of the exhaust manifold.

LOS ANGELES, CAL., Dec. 5—Fourteen Beardsley electrics participated today in the Beardsley Electric Owners' Tour from this city to Orange, Cal. The winner averaged 112.1 miles on a single charge. The average mileage for all the cars participating in the run was 100.1 miles.



Characteristics of type K carbureter showing practically constant ratio of gasoline to air at all rates of air flow



In producing these curves a spring which deflected .5 inch under 1 pound load as against .267 inch in the first set, was used

The Inner Circle

THREE years ago many of the semi-optimists declared that the days of shows were at an end, that novelty in automobiles had almost ceased, that the eventual while not actually arrived was close at hand excepting for the minor alterations which were sure to follow from time to time. Were those theorists here today and confronted with the many changes that are to be seen at the opening of the Grand Central Palace show their logic would have to be entirely revised, and the conclusion drawn that today we seem to be more than ever on the threshold of a great wave of efficiency reform, improvement not by the brute-strength policy of getting more horsepower by adding to the bore and stroke of the motor, more horsepower by lighter reciprocating parts, by more efficient cooling, more regular expansion and contraction of the cylinder walls, by better balance of the crankshaft and connecting-rods, by more rigidity in the crankshaft, by more efficient valve timing, by improved piston rings, by a better system of lubricating the motor—in short, we have need for shows for many years hence. These shows should aim to bring out these finer points of improvement, the buyer should be conducted into this inner circle of improvement and the sooner he realizes that all matters of car cost are not merely questions of wheelbase, tire sizes, motor dimensions, paint and lines, the sooner will the buyer learn how to distinguish between the costly product and the one not possessing such merits of design, material and manufacture.

The Day

ONCE again returns that day in the cycle of months when all should pause on those words spoken over 1,900 years ago, "Peace on earth, good will toward men." In the busiest of industries a momentary pause to gain a wider view of the perspective is essential. Too often during the 12 months we have dug a seemingly endless trench along which we travel, its objective is our business goal, its sides so high that we have lost the view of other endeavors. Our selfishness has increased, our eyes behold but one objective. If for only one day we can get out of our trench, our rut, see the zones in which others operate, see the goals for which others are striving, see the motives that are stimulating others' activities, see the possibilities of other lines of endeavor, see the humanities of our fellow man, then we can go back to our own work with a renewed vim, with a broader vision, with a higher objective, with a more human atmosphere surrounding us.

Used-Car Markets

AIMING to establish a national used-car market report to be issued once every 3 months, a plan already announced by the Chicago Automobile Trade Association, is a very worthy object. The evils of the used, or second-hand, cars have been with us for many years, numerous plans for their solution have been evolved, but this organization is the only one that appears to be operating along feasible lines. Its endeavors do not divulge any of the business secrets of any dealer contributing to the work. The price lists quoted on used cars are based on actual sales, not on appraised values set by committees but on real sales made by dealers. This is the major attraction of the scheme. This gives it reality, not an imaginary value. What Chicago has done other cities should co-operate in and make the national market report a reality. These reports are solely for the dealer and it depends on the dealer as to whether they will eventually be a national success. Every manufacturer should lend his aid to induce his dealers to co-operate in furnishing these used-car values from his zone. These market reports are as essential to the automobile dealer as the metal markets to the metal buyer, or the cotton quotations or grain quotations to their respective buyers.

For years the used-car market has been a mart where uncertainty was the only factor to be counted upon. There were no real standards of value—there was no way in which dealers, car makers or owners could tell the approximate value of any used car. By means of the national used-car reports to be issued by the Chicago association, however, these conditions will be remedied, order will be brought out of chaos and the trade will profit correspondingly.

U. S. Output 515,000 1914 Cars, $485,000,000

According to Chamber of Commerce—Trade Conditions Excellent—Ninety-Three Plants Reported On

NEW YORK CITY, Dec. 19—According to General Manager Alfred Reeves of the National Automobile Chamber of Commerce, over 515,000 cars have been manufactured in the United States during the past 12 months, the wholesale value of these being given as over $485,000,000. These figures place this country far in advance of the balance of the world in automobile and motor truck production.

Mr. Reeves returned yesterday from a western trip which completed travel that during the past 7 months took him to all the factories of the ninety-three members of the chamber. His round of the plants included forty-two cities in eleven different states, from Massachusetts and Virginia in the east to Wisconsin and Missouri in the west.

Trade Conditions Excellent

"Trade throughout the country has been excellent, considering conditions," said Mr. Reeves, "and the makers, as a class, are in good shape. They have lost the export trade in passenger cars to a large degree, but of course, truck figures have increased as a result of the war.

"My visits to the ninety-three plants and conferences with the leading men in the industry," continued Mr. Reeves, "indicate that the present position of the automobile trade has been attained only by concentrated efforts on the part of great engineers and industrial leaders who could forecast the future, and who co-operated through the N. A. C. C. with a view of attaining, in the quickest possible way, the present enviable condition. Combined with this was scientific manufacturing by men schooled in economy, who had efficiency for the keynote in every department of their plants. As a result, greater values than ever before are being offered, and the former sheds that were used for factories have been supplanted by wonderful structures of cement, steel and glass, equipped with the most modern machinery.

"In my rounds, I was forcibly impressed with the readiness of car makers to supply every demand of the public. There is no inclination to force special types, and it is this that has hastened the increased buying of automobiles. Our makers supply cars small or large; low powered or high powered and seating two or seven passengers. They supply cars that are dreams of luxury and others that are mainly for utility. They have been willing to furnish anything from one to eight cylinders, and with conveniences undreamed of a few years ago.

"Prices would appear to be almost at the minimum point, provided quality is to be maintained, materials and labor, which is incidentally 47 per cent. of the list price of the car, are most important in any manufactured article, and if skilled making and good materials are to continue in use, there would appear to be small chance of any lower prices for cars of the present type. It is worth noting that the high priced cars continue in constant demand, although of course the greatest increases have been made in the moderate priced cars that approach within the buying range of an increasing number of people."

Fenders on Chicago Motor Trucks by March 1

CHICAGO, ILL., Dec. 19—Provided a practical device is discovered in a series of tests to be started immediately after Christmas, all motor trucks operating in the city of Chicago must be equipped with fenders on and after March 1, 1915.

This was the bomb exploded in the ranks of the commercial car dealers and users by the city council and police this week. It is an old bomb with a new fuse. Already there is one ordinance, passed in June, 1913, and providing for the carrying of fenders on motor trucks, on the statute books, but it never has been enforced for the reason that it does not stipulate what kind of device shall be carried. The new ordinance, which was passed in October, but which was published for the first time this week, is an amendment to the old one and provides for the holding of a series of tests to determine upon a practical device.

The tests, which will be held under the second deputy superintendent of police, will be made of all designs submitted before December 24. Three plans already have been received. If other plans are received after the holidays, another series of tests will be conducted the first of the new year.

The tests will be made upon three dummies, representing a man, a boy and a child, in various attitudes and at speeds of 3, 7 and 15 miles an hour for use on trucks of 1-ton capacity and greater. The standard size of fender for use on commercial vehicles of 1-ton capacity or more must be attached to a standard truck of 3-tons capacity. A smaller sized fender, if submitted, must be attached to a motor vehicle of less than 1-ton capacity, not of the cyclecar or motorcycle type.

The fender to be approved must comply with several general specifications. According to the ordinance, the length, width and height of the fender shall be of a minimum consistent with the desired protection and at the same time not impede traffic, it shall have resiliency, be adaptable to varying road conditions, be reliable in operation and efficient of mechanism, shall interfere as little as possible with the operation of the truck, be neat in design and appearance and of a reasonable cost so as not to impose unnecessary hardship upon the owners of commercial vehicles.

If the ordinance is enforced, it will affect the owners of 1,911 trucks of 1-ton capacity or over.

A meeting of truck dealers and users has been called by the Chicago Automobile Trade Assn. for Tuesday noon, when the ordinance will be discussed.

Freight Increase Covers Cars and Parts

NEW YORK CITY, Dec. 21—The 5 per cent. freight rate increase asked by the railroads in Official Classification territory was granted last Friday, December 18, by the Interstate Commerce Commission. There were some exceptions, including coal, iron ore and lake-and-rail rates, but motor cars, parts and accessories are covered by the increase.

Official Classification territory is practically that east of the Mississippi river and north of the Ohio and Potomac rivers. Central Freight Assn. territory is that part of Official Classification territory west of Buffalo.

When the first decision was handed down granting a partial increase and applying it to Central Freight Assn. territory it did not affect through rates between points in the territory and points outside; the same rule applies to the latest decision; for example, rates between Boston and San Francisco will not be affected if they are through rates, but if the rate is local to the Mississippi the 5 per cent. increase will apply to the eastern half of the rate.

Shipments by rail between New York and Buffalo and thence by boat to Detroit will not be affected under the lake-and-rail exception, but all-rail shipments between New York and Detroit will be covered by the increase.

The rates are to go into effect 10 days after their publication by the railroad companies; the latter are working out their tariffs now, but those familiar with this task state that it may be February 1 or March 1 before the increases can be made to apply.

NEW YORK CITY, Dec. 18—The Electric Storage Battery Co., Philadelphia, Pa., has declared the usual quarterly dividend of 1 per cent. each on its common and preferred stocks, payable January 2 to holders of record December 21.

California State Speed Law Supreme

SAN FRANCISCO, CAL., Dec. 15—As a result of the recent decision of the Appellate Court of the Third District of California, that state is one of the first in the United States in which a uniform speed law for motor vehicles exists. The ruling of the court, which is a final decision, holds that the present state motor vehicle act supersedes municipal ordinances covering the same subject, and towns and cities cannot enforce any local regulations.

Hub Dealers Win Separator Fight

But Must Minimize Fire Risk or Separators Will Be Required —U. S. Tests Armored Trucks

BOSTON, MASS., Dec. 19—The Boston automobile dealers and proprietors of garages have won their fight against the adoption of separators in all their places of business as proposed under the new fire hazard law, and outlined by John A. O'Keefe, the commissioner in charge of that work. The results are now dependent upon the men operating such places to see that they run their places so as to minimize the hazard, or separators will be ordered installed. When the matter was first broached Commissioner O'Keefe gave a hearing to the motor interests after which he put it up to them to form a committee to cooperate with him and furnish suggestions.

President J. S. Hathaway of the Massachusetts Garage Assn. appointed a committee, to go over the matter and to formulate regulations. Blanks containing thirty questions were sent to 250 garage and service stations in Greater Boston. These were filled out by 121 owners, and then the data were carefully compiled. Then suggestions were evolved, and submitted to President Hathaway. He had a conference with Mr. O'Keefe and submitted them to him. They were as follows:

We would suggest that when any person purchases gasoline in small quantities from a garage, to be used outside a garage, that a record be kept of the name and address of said purchaser.

Make it unlawful to use gasoline for any other purpose in garages than the filling of tanks in automobiles.

No gasoline to be used by industrial institutions, tailors, cleansing establishments, dyers, etc., without special permit from the fire commissioner, and a record to be kept showing in what manner gasoline is disposed of.

Upon investigation we find that there is more danger from gasoline used by industrial institutions, cleansing establishments, etc., than from that used by garages.

A printed card, approved by the commissioner, should be placed upon the floor of every garage, public and private, stating that the use of gasoline other than for motors is prohibited. This card to be signed by the fire commissioner.

If clause 66 of the laws and regulations governing such fluids is enforced there will be no need of installing a separator, in our opinion.

Garages to be supplied with a complete set of these laws and regulations regarding the use of gasoline, etc.

We would suggest that a law be put into effect to prohibit the storage of gasoline in garages other than that kept in the tanks of automobiles, storage tanks and portable tanks.

The storage of gasoline in cans to be kept in a vault outside the garage building, same distance required for gasoline tanks. This vault to be kept locked except when in use.

Rules by January 15

Commissioner O'Keefe intends to promulgate a set of regulations to go into effect on January 15 covering this matter. These rules have not been fully determined yet, but the Commissioner told THE AUTOMOBILE correspondent today that he had decided not to insist upon separators.

"I have framed one rule to provide that if upon examination following the recommendation of Fire Department chiefs, it is found that any garage owner is allowing gasoline to go into a sewer that proprietor will be obliged to put in a separator at once. There will be allowed without special permits a portable tank containing 55 gallons in the garage. Also one can containing one gallon of gasoline. The proprietor may use a tank buried under the building if it is piped to the garage; or a tank buried outside the building, or both. Sets of regulations will be provided for every floor. Special permits may be given for a larger amount of gasoline than that provided above, but in rare cases only, and when its need is really proven. There is to be a special public meeting called to go over the matter at which all interested, including fire department heads, will be present to consider the whole subject. After the regulations are put into effect inspectors will visit garages to note if the law is being observed, and those who do not live up to it will have to install separators or their license to do business will be revoked. By impressing upon every one that more care should be used, such as obeying the 'No Smoking' signs, and having the motor stopped when the tanks in cars are being filled, together with observing our regulations, I believe the danger will be minimized to a great extent."

244 White Trucks Go to Russia

CLEVELAND, O., Dec. 21—A train-load of seventy freight cars loaded with 244 motor trucks was shipped by the White Co., Saturday, destined for the Russian army; the equipment was made up of different truck capacities, the sale being made direct through the White dealer at Petrograd. This shipment is to go to New York, thence by steamer through the Panama Canal, and across the Pacific to Vladivostok, and thence over the Trans-Siberian railroad to Petrograd. Col. J. Baldwin, the special commissioner of the Russian Imperial government, is in Cleveland, and has placed an additional order with the White Co., for 200 trucks. According to Col. Baldwin, future shipments will be sent via the Panama Canal in preference to the Archangel route, it being deemed safer from molestation by the German navy, and also because since the Russian-Japanese war the Russian government has kept a steamer route to Vladivostok open by the use of enormous ice crushers for practically the entire winter season.

Government Experiments with Armored Cars

WASHINGTON, D. C., Dec. 19—Some experiments are being conducted by the army ordnance department with improvised armored motor cars. These were obtained by purchase of motor chassis of the four-wheel-drive type, on which is being installed armor plate of a thickness and character similar to the shields of field artillery guns. It is estimated that such a car with armor will cost about $5,000.

Anderson Goes from Chalmers to Hupp

DETROIT, MICH., Dec. 21—Lee Anderson, well known in the industry and connected with the Chalmers Motor Co.'s advertising department for 5 years, has resigned to become advertising manager of the Hupp Motor Car Co. He succeeds Frank Mooney, who recently resigned. Anderson takes up his new duties January 1.

250 Owen Cars with Entz Gearset for 1915

NEW YORK CITY, Dec. 21—R. M. Owen & Co., 142nd street and Fifth avenue, this city, has secured a factory of 50,000 square feet at this address and has begun the manufacture of 250 Owen cars with the Entz electric gearset for 1915. In the new factory the electric gearset will be manufactured in its entirety and the assembly of the remainder of the chassis carried out. The Owen company is owned outright by R. M. Owen who was sales agent for Reo and Premier for several years, Stoughton A. Fletcher, banker of Indianapolis, and who is now heavily interested in numerous motor car businesses, together with R. A. Rainey of the large coke industry in Pennsylvania.

The new car as a touring model will list at $3,700 and as a three-passenger roadster at the same price. Production is already well under way, the first lot of ten cars being nearly completed. A six-cylinder motor 3 3-4 by 5 will be used, together with American Ball Bearing Co. axles, and Houk wheels.

By using the Entz type of electric gearset the conventional clutch and gearset are eliminated and with them go the magneto, electric motor starter and electric generator, the units of the electric gearset supplying all of these parts. The striped chassis weighs 3,150 pounds. The wheelbase is 136 inches, tires 35 by 5 and flat semi-elliptic springs are used in front and rear. Only a small Willard starting battery is carried.

In the electric gearset are two units, one called a clutch generator and the other a conventional electric motor. The clutch generator takes the place of the flywheel and performs two functions, first that of an electric clutch and second a generator of electricity. The second unit is an electric motor which is mounted back of the clutch generator. This electric motor uses current generated by the clutch generator and helps the gasoline motor to drive the car. There is a mechanical reverse.

Report Favors Federal Roads

Congressional Committee Advises That Comprehensive Plan for Road Building Is Urgent

WASHINGTON, D. C., Dec. 19—Within the next few days the joint congressional committee on federal aid for good roads will issue a voluminous report in which will be set forth the fact that incalculable advantages will accrue to the United States from the construction of a system of model highways throughout the country. The report is now before the committee for approval and the correspondent of THE AUTOMOBILE has been privileged to make certain excerpts from it of interest to motorists.

It is an interesting fact that the committee in this report has refrained from recommending any specific plan of action, although it had before it numerous proposals, which included former Senator Bourne's bill providing for an issue of 50 years' bonds aggregating $500,000,000.

Of particular interest in the report are the conclusions arrived at by the committee and some of these are as follows:

Congress should proceed at once to devise a broad, comprehensive plan for federal aid to the building of model roads.

The supervision of the government's highway building activities should be intrusted to a congressional commission, not an adminstrative bureau.

Care should be exercised that federal aid be scientific and effective and not degenerate into a "pork barrel" raid on the national treasury.

First class roads in this country would reduce the cost of living, improve business and ameliorate educational and social conditions in rural communities.

More than $10,000 and 2 years' time has been devoted to a comprehensive study of the good roads problem and a vast amount of information has been collected in this country and in Europe. The committee's report expresses the opinion that federal aid to state road building once undertaken never will be abandoned and therefore should be entered upon only after the most exhaustive study of the problem.

Denver Club Inaugurates New License Plan

DENVER, COLO., Dec. 20—Motor car owners belonging to the Denver Motor Club are being saved a great deal of time and inconvenience by a plan the club has inaugurated to secure the 1915 state licenses for all its Denver members. Official application blanks have been mailed to the 1,100 members living in the city and county of Denver. They can fill out these blanks at home, bring them to the club's headquarters, have the required notary work done in a few minutes and then let the club obtain a large number of licenses at one trip to the office of the secretary of state.

12 Miles an Hour Maximum Speed in Omaha

OMAHA, NEB., Dec. 19—Omaha is now lining up with the rest of the big cities in the United States in regard to proper traffic laws. A new traffic code became effective Thursday requiring lights on all vehicles, whether motor-drawn or otherwise, and extends the district wherein 12 miles per hour is the maximum speed. An ordinance requiring that the driver of every motor-driven vehicle, whether he be the owner of a limousine or the chauffeur of a taxicab, to take out a chauffeur's license has also been introduced to the city commission and will soon be passed on. With the license will go one of the metal tags.

Ten Exhibits for Salon

NEW YORK CITY, Dec. 21—France, England, Italy and the United States are represented by the ten exhibitors who have already taken space for the importers' automobile salon to be held at the Astor Hotel January 2 to 9. The exhibitors who have already taken space are the representatives in this country of De Dion-Bouton, Fiat, Isotta-Fraschini, Lancia, Renault, Rolls-Royce, Simplex, Sheffield-Simplex, Holbrook Co. and Brewster & Co.

$700 Yearly Upkeep Per Mile Is Not Excessive for Macadam Roads

NEW YORK CITY, Dec. 19—Well-constructed gravel roads will sometimes sustain years of traffic without showing marked deterioration, even when there has been no maintenance. Such roads sometimes even improve during the second season; more frequently, however, they show ruts or the formation of chuck holes. It can not be expected that the average life of a gravel surface will be greater than that of a macadam surface. The average interval for resurfacing macadam roads is between 6 and 7 years. If a sum equal to two-thirds of the original cost of the gravel surface itself is provided for renewals at 6-year intervals, it should be estimated at from $150 to $250 per mile per year. If $30 is then allowed for annual dragging and small repairs, the total annual cost of repair and maintenance of gravel roads would be from $180 to $280 per mile. The annual cost of strict maintenance is sometimes below $30. In Bennington County, Vt., during 1912, 175 miles of gravel roads were maintained at a cost of $20.70 per mile. The annual cost of maintenance and repair on sand-clay roads, including all necessary resurfacing at periodic intervals, should not be fixed at less than 10 per cent. of the original cost.

The cost of repair and maintenance of water-bound macadam roads has been determined with some considerable exactness from Massachusetts figures and checked by resurfacing charges in other states and in Germany. From $100 to $125 per year ordinarily pays for necessary small repairs, such as patching, cleaning culverts, etc., and from $400 to $425 per year is the necessary annual charge for resurfacing at periods varying from 6 to 7 years. The sum of $525 per mile, on an average, should therefore absolutely maintain macadam roads if changes and increases of traffic are not excessive. It must be understood, however, that in many instances where macadam sufficed for the volume and character of traffic prior to 1906, it will not withstand the action of the motor vehicle traffic, which has developed since that time.

Many miles of ordinary or water-bound macadam road have been resurfaced with bituminous materials and many miles of new bituminous-macadam road have been constructed. The logical maintenance of such highways is a surface treatment with bituminous material and rock screenings, clean gravel, or sharp sand. The cost of such surface treatment is from 4 to 12 cents per square yard, and it may be expected to last from 1 to 3 years, according to the density of traffic and the success of the application. Theoretically, perfect surface treatment would constitute absolute maintenance for a bituminous-macadam road. Such maintenance is seldom or never realized and bituminous-macadam roads doubtless require resurfacing at intervals. The cost of such resurfacing is not yet known.

The average cost for repair and maintenance of 7,300 miles of highway in Connecticut, Massachusetts, New York, New Jersey, and Rhode Island for the year 1912 was about $800 per mile. A large part of this money was expended for bituminous resurfacing and bituminous surface treatment. There is some question whether the expenditure correctly measures the average cost of repairing and maintaining bituminous-macadam roads. In the State of New York, however, for the years 1911 and 1912 the average cost for repair and maintenance was $724 per mile upon a total average of 2,861 miles. The annual cost of repair and maintenance on Massachusetts state roads for the years 1910, 1911, and 1912 was, respectively, $642, $647, and $676 per mile for about 850 miles. For the most part these figures for New York and Massachusetts represent the cost per mile of resurfacing with bituminous material and of maintaining bituminous-macadam and water-bound macadam roads by surface treatment with bituminous material. It is clear, therefore, that $700 per mile is not an excessive estimate at present for the annual cost of all repair and maintenance of bituminous-macadam roads.

Wisconsin Buys 18,000 Cars

Business Divided Among 1,202 Dealers, Average 15 Cars Per Dealer

MILWAUKEE, WIS., Dec. 22—A most gratifying trade situation in Wisconsin for the year 1914 is reflected by the comparative report of registrations of motor cars in private hands for the last 3 years, compiled for THE AUTOMOBILE by the motor registry division of the secretary of state's department. There were registered in Wisconsin this year 18,515 more privately-owned cars than in 1913, indicating that approximately 18,000 new cars were distributed in this state during the anual period now closing. The business was divided among 1,202 dealers, who sold on the average of 15 cars each. In 1913 the figures indicate a sale of 10,068 new cars for the year, distributed among 1,393 dealers.

The comparative statistics follow:

	1912	1913	1914
Automobiles at $5 each	$24,578	$34,646	$53,161
Motorcycles at $2 each	4,060	6,120	7,880
Dealers at $10 each	1,052	1,393	1,202
Total revenue	$136,270	$199,400	$293,585

The fact that Wisconsin assimilated more than 18,515 cars in a year that probably will go down as one of the worst, industrially, in American history, leads to the belief that this state can take care of at least 25,000 and possibly more cars during 1915, which is expected to be a boom year. It is figured that only 6,500 to 7,000 of the 18,515 cars purchased in 1914 were Fords. The population of Wisconsin is figured today at 3,000,000, and the 1914 registration shows that there is a car for every 60 persons in this state. The most important tradesmen are of the opinion that until the ratio contracts to one car to every 25 of population, their market is an attractive one. Thus there seems to be no reason why 1915 should not be the best year in motor history.

Wisconsin registration figures are reliable as a basis for figuring the number of new cars absorbed by the state for the reason that Badger licenses are annual and owners must apply for new licenses at the close of each year, for issue on January 1 of the succeeding year. Owners who dispose of a car may transfer the old license to the new for 50 cents and the purchaser must take out a new license at $5, so that such transfers do not alter the figures and the yearly gain actually represents the number of new cars purchased during the year.

The decrease in the number of dealers for 1914 compared with the previous year is taken to mean that the business of selling cars is becoming more stable and a matter of the survival of the fittest. The number of agents is 191 less than in 1913. This number probably represents the host of so-called curbstone dealers who are gradually being driven out of business or driven into legitimate agency business.

It will be seen from the report that Wisconsin motorists pay a tribute of approximately $300,000 per annum for the privilege of driving their cars over the public streets and highways. Private owners pay $5 per car; motorcyclists $2, and dealers $10. The private owner stands the greatest share of the burden, or $266,000. The manner of distributing the revenue, however, removes the pain of the sting. After the cost of adminstration is deducted, the net revenue is transferred into the highway funds of state and county. The state aid fund receives 25 per cent. of the net revenue, while 75 per cent. is turned back into the highway funds of the counties according to the amount paid in from each county for licenses.

N. Y. Registrations Gain in Value $354,411.59

NEW YORK CITY, Dec. 21—Motor registrations in New York up to and including December 15, netted that state a total of $1,525,855.86, an excess of $354,411.59 over the same period of last year. So far this year 167,930 automobiles were registered and 66,113 chauffeurs licensed. These figures reveal about 20 per cent. increase in fees, 26 per cent. increase in registrations and 19 per cent. increase in the number of chauffeurs licensed, there being 132,251 motor cars registered and 56,228 chauffeurs licensed in 1913.

Of the total number of motor vehicles registered, 150,678 are pleasure cars, 17,252 commercials and 2,368 owned by non-residents. One of the most notable features shown by the registration figures is that the bulk of cars or 75,042 motor vehicles are less than 25 horsepower; 50,971 less than 35; 19,943 less than 50, while only 1,298 were rated at 50 horsepower or more.

54,600 Licenses Issued in Missouri

ST. LOUIS, MO., Dec. 18—There have been issued up to December 15, in Missouri, 54,600 licenses. Of this number St. Louis had the greatest number of registrations with 12,004, while 6,749 were issued to residents of Kansas City. For the same period last year St. Louis had 9,789 plates and Kansas City, 5,494. For the entire year of 1913 the registration for the whole state was 38,140.

During the past month, November, ninety-two cars were registered from St. Louis. Thirty-five were Fords.

Hexter Truck Makers Assign

NEW YORK CITY, Dec. 19—The Roland Gas-Electric Vehicle Corp. has assigned for the benefit of its creditors to Clifford G. Ludwigh. This company was formed last November to manufacture a new type of gasoline-electric truck designed by P. K. Hexter. It had a capital of $200,000. War conditions, it is stated, coupled with the closing of the stock exchange, on which nearly all of the backers operated, interfered with the manufacturing work.

A petition in bankruptcy was filed against the company,

Automobile Securities Quotations

NEW York City, Dec. 22—A slightly weaker tone was apparent in the automobile securities market during the past week. This was not peculiar to the automobile securities, all other stocks being affected more or less. What declines there were, however, were not important and the market as a whole might be characterized as steady. Some of the week's changes are significant of the general trend. General Motors common was 5 1-2 points below last week while the preferred was slightly ahead. Firestone preferred gained 1. Goodyear and Goodrich stocks were slightly lower. Kelly-Springfield common lost 3 points while the first preferred gained 1 1-2. Maxwell stocks were a little stronger. Stewart-Warner gained 5 on the common and 1 1-2 on the preferred, U. S. Rubber 3 3-4 on the common and 2 on the preferred and White preferred rose 1 point. Willys-Overland common gained 3 points and preferred 4.

4,672 Motor Vehicles in Montreal

MONTREAL, QUE., Dec. 25—A census taken late this summer of the number of automobiles in the Province of Quebec shows 7,317 motors, 7,025 cars and 292 trucks. The city of Montreal has alone 4,422 cars and 250 trucks the remaining number being distributed throughout the Province.

Motometer Wins Appeal in Patent Suit

NEW YORK CITY, Dec. 19—The Circuit Court of Appeals has affirmed the preliminary injunction granted May 21 to Harrison H. Boyce and the Motometer Co., Inc., in its suit against the Stewart-Warner Speedometer Corp., charging infringement of patent No. 1,090,776 covering the Motometer, a device for showing cooling water temperature.

The patent in question was issued March 17, 1914 and the suit was commenced April 11, 1914. The order to show cause why the preliminary injunction should not be granted was made without notice and served on the Stewart-Warner Speedometer Corp., April 14. The latter filed its answer charging lack of invention in the Motometer patent May 1. On May 16, Judge Hand, in the U. S. District Court for the Southern District of New York, granted the preliminary injunction prohibiting the manufacture and sale of the Stewart-Warner radiator thermometer. The suit was originally brought against the Stewart-Warner Speedometer Corp. of Virginia, and the Stewart-Warner Speedometer Corp. of New York, but the Virginia corporation was not made a party to the suit, being outside the jurisdiction of the court.

Judge Rogers, of the Circuit Court of Appeals, held that, although there had been no prior adjudication of the validity of the patent, the lower court had not abused its discretion in granting the injunction. Some significant extracts from the decision follow:

"The complainant's device embodies the idea primarily of affording protection against the great evil of engine over-heating, for which previously there had existed no remedy."

"The defendant claimed that the complainant's device was anticipated by the prior art..........................but an examination of the patents referred to convinces us that there is absolutely nothing in the claim of anticipation by the prior art. The prior patents do not disclose or in any way suggest the invention of the patent in suit."

"The evidence shows that prior to 1912 there was nothing known in the automobile art which would enable one running an automobile to discover an undue heating of the engine in time to rectify it and avoid irremediable damage. It was not until complainant's Motometer was invented that any instrument existed which could be used in connection with automobiles to give warning of a dangerous condition of the engine. In the face of the affidavits which were presented, the utility of the complainant's device cannot be doubted."

U. S. Tire Co. Concentrates Production

NEW YORK CITY, Dec. 21—The United States Tire Co. has decided to concentrate the entire automobile tire production in the Hartford and Detroit plants. All solid tires for motor trucks, carriages and vehicles of all sorts will be made in Providence and bicycle and motorcycle tires will be made exclusively at Indianapolis. The company will continue its policy of furnishing the G. & J. brand of automobile tires, not through its branches, but through the number of large distributing agencies handling this brand.

Crescent Delivery Car Makes Appearance

LOS ANGELES, CAL., Dec. 20—A new light delivery car has made its appearance in Los Angeles. The machine is known as the Crescent car and has been placed on the market by the Mission Motor Car Co., of the Southern California city, designed to meet the needs of the tradesman who needs a car of no greater capacity than 600 or 800 pounds.

Atwater Kent to Build New Factory

PHILADELPHIA, PA., Dec. 19—The Atwater Kent Manufacturing Works, Wayne Junction, has under way the construction of a new brick factory building adjoining the present structure that when completed will give the company two and one-half times the present available floor space.

Nyberg Plant to Be Reopened and Operated

INDIANAPOLIS, IND., Dec. 21—The plant of the Nyberg Automobile Co., Anderson, is to be re-opened and operated at once. Albert C. Barley of Marion has acquired full control from James W. Sansberry, a banker. The company has been in litigation, Barley having filed suit against Sansberry demanding an accounting. In a compromise of this suit, Barley acquired control.

LOUISVILLE, KY., Dec. 19—Perplexity of Louisville motorists as to how to obtain their 1915 licenses was removed this week when H. L. Ramsey, deputy state commissioner of motor vehicles, attending a special meeting of the Louisville Automobile club directors, announced that an arrangement had been made with the secretary of state whereby the licenses would be issued through the office of the commissioner of motor vehicles.

NEW YORK CITY, Dec. 18—The Kelly-Springfield Tire Co. has declared a dividend of 1 1-2 per cent. on the common stock, payable February 1, 1915, to the stockholders of record at the close of business January 15, 1915. It has also declared quarterly dividends of 1 1-2 per cent. on the 6 per cent. preferred stock and 1 3-4 per cent. on the 7 per cent. second preferred stock, payable January 2, 1915, to stockholders of record at the close of business December 15, 1914.

Bretz Company Files Certificate

ALBANY, N. Y., Dec. 21—The J. S. Bretz Co., 250 West Fifty-fourth street, New York City, importer of F. & S. ball-bearings, filed a certificate of dissolution with the secretary of state on November 28.

Market Reports for the Week

This week's market reports showed a few changes in the metal, rubber and silk quotations. In the metal market, both coppers underwent a drop of $0.00 1-8 per pound. The tone of the copper market is weak, although producing interests are still making little effort to attract business. There is small demand from the consumers and second hands are more anxious to sell at concessions. Tin also experienced a decline, a weaker tone having developed this week, in sympathy with the same in London. This metal closed at $33.50 per 100 pounds, a drop of $0.88. Both Bessemer and open-hearth steels, however, went up in prices, closing at $18.50 per ton, at a gain of $0.50. The crude rubber market this week retained a firm tone with no material change. Up-River fine Para closed at $0.76 at a gain of $0.03. Para is very scarce, as there is apparently little obtainable at less than $0.76 a pound. The consumers were purchasing sparingly, and there was little doing among the dealers. Reports from London state that rubber is easier for plantation.

A report states that arrangements soon would be completed looking to a removal of the embargo under restrictions against the export of rubber from the British colonies to the United States. While the details of the arrangements have not been fully worked out the State department has been given to understand that the American importers of rubber will be required to give guarantees that none of the product shall reach Great Britain's enemies.

Repairs, 22.7 Cents per 1,000 Miles

Twenty Winton Prize Winners Drive 359,116 Miles for $49.97

NEW YORK CITY, Dec. 18—The Winton Motor Car Co.'s seventh annual repair expense contest, begun on April 1, 1914, and ended on November 30, was won by John Grau, chauffeur for J. F. Casey, of Pittsburgh, who drove his Winton Six 24,362 miles with no repair expense. The twenty winners of Winton prizes drove 359,116.2 miles with a total repair expense of $49.97, or an average of 22.7 cents per 1,000 miles. For the seven contests, 110 cars have traveled 1,689,076.2 miles with a total repair expense of $383.68.

The year 1911 seems to have the best record so far as total mileage and total repair expense are compared. That year twenty cars made 394,333.9 miles with a total repair expense of $20.88. The next best year is 1913 when twenty cars totaled 294,774.8 with a total repair expense of $31.46. In 1910 ten drivers went 165,901.9 miles at a total repair expense of $6.96. The first year the contest was started, 1908, ten drivers went 65,687.4 miles at a repair expense of $15.13.

The winner receives the prize of $1,000. The second prize of $500 went to W. H. Franklin, chaffeur for the Boston Last Co., Boston, Mass., who drove a Winton Six 27,432.6 miles at a repair expense of $18. Third prize, $250, went to W. M. Newsome, who won third prize last year. His mileage with a car belonging to M. R. Hirsch, Atlanta, Ga., was 22,175 with no repair expense.

The following list gives the seventeen remaining winners, who received each a prize of $100:

Name.	Owner	Mileage	Total Repair Expense
F. C. Batt	State of New York	22,208.9	$20.15
Thomas Brown	M. J. Finnigan, Worcester, Mass.	19,445	1.20

M. H. Murphy	R. T. Heitemeyer	12,815	None

The judges were: J. A. Dickson, *Youth's Companion;* D. G. Newton, *Cosmopolitan Magazine;* G. C. Pierce, Associated Sunday Magazines; R. M. Banhart, *National Geographic Magazine*, and R. G. Howse, *Literary Digest*.

Indianapolis Seating Capacity Raised to 75,000

INDIANAPOLIS, IND., Dec. 19—Construction of a new grand stand, seating 15,000 people, has been started on the south turn of the course, raising the total seating capacity of the plant to 75,000, which is equalled only by the new Yale bowl at New Haven. Over a mile of grand stands, the longest in the world, will soon be a speedway fixture.

Additional improvements are the erection of a communal garage, accommodating forty cars, in back of the judges' stand,—the old garages having been torn down, and their site turned into parking space,—the widening of the track on the inside by 15 feet, and the erection of a concrete safety wall all around. A club house for drivers, complete with gymnasium, tennis courts, and swimming pool, are contemplated for next spring.

Omaha Speedway Opening July 5

OMAHA, NEB., Dec. 19—July 5 was tentatively selected by the management as the date for the opening race meet at the new automobile speedway here.

Chicago Speeders Give Appearance Bond—No Jail

CHICAGO, ILL., Dec. 17—No longer will Chicago motorists have to go to jail for infractions of the local ordinances which apply to the control of traffic. A new order goes into effect January 1 which will change all this. Chief Justice Harry Olson of the municipal court, and Max Korshak, assistant corporation counsel, have approved an appearance bond which violators may sign and go on their way. The next day they must appear in court or a jury will be called and a judgment entered fining the violator. An execution then will issue and the accused either must pay or go to jail.

Republic Rubber to Open Foreign Branch

YOUNGSTOWN, O., Dec. 21—The Republic Rubber Co., this city, is going to open a European branch in London early in the new year and Frank V. Springer, manager of the railroad sales department of the company for the last 10 years, will be in charge. Mr. Springer has had headquarters in New York City. The London branch will care for continental business as well.

1 Hour Limit for Parking Detroit Cars

DETROIT, MICH., Dec. 19—Beginning December 21, automobiles found parked in front of stores and offices more than 1-hour are to be removed by the police either to special parking places or to streets where they will not interfere with the shoppers or with traffic. The owners are to be called before the traffic department officers and may be fined.

The policemen specially detailed for that work will be provided with stickers to be affixed upon the car tires. Upon the sticker the policeman will mark the time or hour when this sticker was placed upon the tire and when returning to check up the cars and upon finding cars parked beyond the allowed time of 1 hour he will have the car removed.

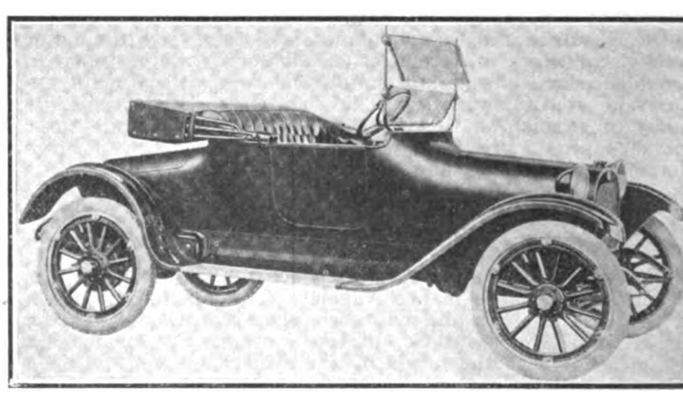
Lozier Creditors' Meeting Dec. 29

DETROIT, MICH., Dec. 19—Efforts to re-organize the Lozier Motor Co., have not been abandoned notwithstanding that 10 days ago the company was declared bankrupt. A committee of creditors acting on its own responsibility has formulated plans for a re-organization of the company and has arranged for a general meeting of creditors to be held December 29 at 2 p. m. in the United States District Court, in Detroit.

Two Petitions for Hassler Co.

INDIANAPOLIS, IND., Dec. 19—The United States Court at Indianapolis has under consideration two petitions concerning the Hassler Shock Absorber Sales Co. One, filed by Robert H. Hassler, asks for the appointment of a receiver, and the other, filed by Robert H. Hassler, Inc., Asa P. Romertson, doing business as The Auto Exchange, and the Advertisers' Press, creditors, asks that the concern be adjudged bankrupt. The state courts on November 27 appointed Homer L. Archer receiver for the company.

INDIANAPOLIS, IND., Dec. 19—Earl Cooper has been engaged by the Stutz Motor Car Co., Indianapolis, Ind., to drive for it in the Vanderbilt and Grand Prize Races which will be run at San Francisco.



Dodge Bros., Detroit, has supplemented its touring model by a roadster body on the same chassis of 110 inches wheelbase. Like the touring model, the roadster is an all-steel construction, including the frame. Doors are wide and have concealed hinges and handles, and there is a sloping rear deck with a door giving access to a spacious luggage compartment. The characteristic oval, molded fenders are fitted. Price $785, same as touring car

Car, Truck and Accessory Plants Expand

(*Continued from page* 1174)

The Houk Mfg. Co., Buffalo, N. Y., added one story to the one-story machine shop for wheel assembly, giving an increase of 25,000 square feet at a cost of $35,000.

The Hyatt Roller Bearing Co., Newark, N. J., has added a six-story and basement structure 75 by 200 feet, to provide for increased business. This gives an increase in floorspace of 150,000 square feet.

Kelsey Wheel Co., Detroit, Mich., spent $50,000 on new machinery.

The Otto Konigslow Mfg. Co., Cleveland, O., spent $3,500 for new machines.

The K-W Ignition Co., Cleveland, O., has added 28,750 square feet in three buildings as follows, two one-story buildings 65 by 125 feet, and one 85 by 125 feet and an addition 25 by 75 feet. The additions cost $55,000 and new machinery $60,000.

The Leather Products Co., Cincinnati, O., spent $500 for new machinery.

The Lee Tire & Rubber Co., Conshohocken, Pa., added sufficient equipment during the year to increase the output 200 tires per day making the total daily production 1,000 to 1,200 tires.

A new one-story building to be used as a heat-treating department has been added by the Link-Belt Co. to its Ewart works at Indianapolis, Ind. It is 48 by 148 feet and cost $11,000.

About $10,000 was expended by the Lovell-McConnell Mfg. Co., Newark, N. J., on new machinery.

A four-story addition 60 by 20 feet, and having a floorspace of 4,800 square feet has been made the plant of the Mansfield Tire & Rubber Co., Mansfield, O. New machinery to the extent of $20,000 has been purchased.

Paul M. Marko & Co., Brooklyn, N. Y., have occupied larger quarters adding 3,750 square feet. The three-story building is 25 by 90 feet, $50,000. Machinery, $60,000.

One building has been added to the plant of the McCord Mfg. Co., Detroit, Mich., giving an increase of 14,000 square feet. It will be used as a storage and repair department and represents an expenditure of $10,000. New machinery, $6,000.

Metal Auto Parts Co., Indianapolis, Ind., has rented additional space of 8,800 square feet. New machinery, $10,000.

The Mohawk Rubber Co., Akron, O., has added a machine shop, press room, storage building and office, totaling about 30,000 square feet, $50,000. Machinery, $60,000.

The New Departure Mfg. Co., Bristol and Hartford, Conn., has added a five-story and basement structure containing executive offices, light machine departments, inspection and packing and shipping departments at a cost of $250,000. The total floor area of the company's plants is now close to 500,000 square feet.

The New Process Gear Corp., Syracuse, N. Y., has added a new heating plant and made an addition to its office increasing its floorspace 8,000 square feet at a cost of $45,000. Machinery, $175,000.

The Niagara Fabric Mfg. Co., New York City has added 2,500 feet at a cost of $500. Machines $500.

A building containing 20,000 square feet has been added to the plant of the Oakes Co., Indianapolis, Ind., at a cost of $20,000. It will be used for machines and assembling. New machinery, $10,000.

The Osborne & Stephenson Mfg. Co., Plainville, Conn., spent $18,000 for new machinery.

An entire floor of 16,280 square feet has been added by the Perkins-Campbell Co., Cincinnati, O., for manufacturing purposes.

In addition to the original factory at Peru, Ind., having 175,000 square feet, the Pittsburgh Model Engine Co., Pittsburgh, Pa., has a new factory at Pittsburgh which adds 75,000 square feet and represents an expenditure of $600,000. Additional machinery, $150,000.

At an expenditure of $6,250 the C. D. Pruden Co., Baltimore, Md., has added a building 40 by 160 feet giving an additional floorspace of 6,400. New equipment, $1,250.

A four-story addition 300 by 120 feet for building closed bodies has been made by the Racine Mfg. Co., Racine, Wis., which has also added largely to its dry kilns giving the capacity of 200,000 square feet of lumber to be dried at one time. Separate building 80 by 80 has also been added for making wood bendings. The additional floorspace totals 200,000 square feet. Expenditures on the plant amount to $75,000. New machinery, $25,000.

Remy Electric Co., Anderson, Ind., has bought $75,000 worth of new machinery.

The Ross Gear & Tool Co., Lafayette, Ind., has expended $5,000 on new equipment.

Saginaw Sheet Metal Works, Saginaw, Mich., spent $6,000 on new machinery.

The Salisbury Wheel & Mfg. Co., Jamestown, N. Y., bought $2,000 worth of new machinery.

Light Mfg. & Foundry Co., Pottstown, Pa., added $15,000 worth of new machinery.

The right hand wing of the S. K. F. Ball Bearing Co.'s plant, Gothenburg, Sweden, has been added during the past year.

The Sparks-Withington Co., Jackson, Mich., added 50,000 square feet for its nickel-plating and shipping departments.

A new plant consisting of five buildings is occupied by the Standard Machinery Co., R. I. The main building is 75 by 525 feet, the heat treating building 120 feet square, gas plant 40 feet square, power plant 70 feet square and garage 40 feet square.

The Standard Thermometer Co., Boston, Mass., has added a new building 80 by 20, 3,200 additional square feet.

The Standard Welding Co., Cleveland, O., has a new warehouse 240 by 60 increasing the floorspace by 14,400 square feet and is to be used for the storage of rims and bands. It cost $21,000. New machinery, $25,000.

The Stewart-Warner Speedometer Corp., Chicago, Ill., has a new plant which is estimated at $200,000.

Stromberg Motor Devices Co., Chicago, Ill., spent $5,000 on new machinery.

Sunderman Safety Carbureter Corp., Newburgh, N. Y., has added $1,000 worth of machinery.

Swinehart Tire & Rubber Co., Akron, O., spent $15,000 for a new machine.

The Timken-Detroit Axle Co., Detroit, Mich., expended $50,000 on new machinery.

Todd Mfg. Co., Minneapolis, Minn., spent $300 on new machines.

The Van Sicklen Co., Aurora, Ill., started with 8,000 square feet and now has 10,000. It expects to move into a new two-story and basement plant extending into the adjoining buildings in the near future. New machinery, $9,000.

Wagner Electric Mfg. Co., St. Louis, Mo., has added 50,000 square feet at a cost of $160,000 in a four-story building 272 by 45 feet. New machinery, $30,000.

The Warner Mfg. Co., Toledo, O., $50,000, new machinery.

An addition of 7,000 square feet has been made to the machine shop of the Waukesha Motor Co., Waukesha, Wis., $7,500. New equipment, $15,000.

The Westinghouse Air Spring Co., New Haven, Conn. Machinery, $15,000.

The Whitney Mfg. Co., Hartford, Conn., added a steel storage room 50 by 160 feet, giving an increase of 8,000 square feet.

The Willard Storage Battery Co., Cleveland, O., is building an entirely new factory which, when completed, will comprise ten buildings, containing 6 acres of floor area. An idea of the large size of the plant may be gained from the illustration on page 1153.

1914 A Good Contest Year—120 Sanctioned Events

(*Continued from page* 1147)

The 15, 20, 25 and 75-mile 1-mile circular dirt track records were broken by Burman in his Peugeot, the first one at Peoria, Ill., the next two at Springfield, Ill., and the last at Galesburg, Ill.

Fuel efficiency tests were gone into more extensively this year. Such companies as the Buick, Chandler, Franklin, Saxon, Moon, Carnation, Studebaker and Overland held special fuel economy tests. A Buick six made 38.9 m.p.g., and a four, Model B-25 made 22.5 m.p.g. During May the Franklin company held a nation-wide competition, the result of which showed that ninety-four cars averaged 32.8 m.p.g., the highest mileage being 51.2 and the lowest 17.2. A Chandler six made 23.7 m.p.g. and a 1915 Overland model 80 equipped with a Stromberg made 29 m.p.g. In May, 180 Saxons averaged 34.75 m.p.g. Each of the competing cars was driven 200 miles without stopping the engine. The average mileage scored was at the rate of less than 1-4 cent a mile for fuel for each passenger. The transcontinental Saxon averaged 30 m.p.g. for 3,389 miles. A number of the cars averaged more than 47 m.p.g., while the lowest was 26.7. A Studebaker six in a series of 200-mile runs around Buffalo, averaged 15.15 m.p.g. In June a Carnation made 29 m.p.g. in a 24-hour non-stop run around New York City.

Two hill-climbs were held during the year, Atlanta and Uniontown. The Atlanta climb was won by a Pope-Hartford and the record for the hill broken, time 20 2-5 seconds. A KlineKar won the 2-day hill climb at Uniontown, making the best time for the 3-mile ascent, 3.57 4-5.

CASE Force Increased—By reason of heavy orders for tractors and motor trucks for export account, it is reported the J. I. Case T. M. Co., of Racine, Wis., has increased its force to 1,400 men and hopes to bring this number up to 1,800 by January 1. Nearly all of the export orders come from the Case branch at Odessa, Russia, and the material is for war use.

U. S. Reclaiming Works Damaged by Fire—Damage amounting to $75,000 was recently done by fire in the United States Rubber & Reclaiming Co. plant, Buffalo, N. Y.

Morrow Plant to Be Enlarged—The plant, it is stated, of the A. P. Morrow Mfg. Co., manufacturer of automobile parts, Elmira, N. Y., will be enlarged by the construction of a shop costing about $125,000.

Western Auto Supply Will Equip—The Western Auto Supply Co., Kansas City, Mo., recently incorporated with a capital stock of $20,000, will equip a plant for the manufacture of automobile accessories, etc.

Goodrich Adds $5,000 Addition—A permit has been granted by the building department of Akron, O., for a two-story addition to the plant of the B. F. Goodrich Co., to cost $5,000. It will be an addition to plant No. 26.

Pierce-Arrow Purchases Site — The Pierce-Arrow Motor Car Co., Buffalo, N. Y., has purchased a site at Elmwood avenue and the New York Central R. R., upon which will be erected a plant for the manufacture of commercial vehicles.

New Plant for Akron—Another rubber company will be started in Akron, O., with local men operating it, to make automobile tires. It will be known as the Rubbertown Tire Co. The capital is $10,000. O. J. Schwab, M. Greenberger and J. F. Darcy are interested.

Jones Will Operate Two Plants—J. J. Jones, of the Jones Six Co., Wichita, Kan., announces that that company will operate two factories in that city. The old Neely furniture store building, which was purchased recently, is being transformed into an automobile factory. The company is contemplating erecting a truck factory also.

Mecca Plant in Trenton—Negotiations have been made by the Mecca Tire Co., Philadelphia, Pa., for the purchase by it of the American Lamp & Brass Co., situated on Mulberry street, Trenton, N. J. The land upon which the plant is located is 385 by 300 feet. The plant comprises six brick buildings, each 30 by 90 feet. Five of the buildings are 2½ stories high, while one is 3½ stories. The company, it is said, will begin operations in March. The concern is incorporated under the laws of Delaware for $500,000.

Milwaukee Co. Adds—The C. H. & E. Mfg. Co., 321 Mineral street, Milwaukee, Wis., manufacturing gasoline engines, tractors, gasoline cars and portable sawrigs and similar equipment, has awarded contracts for the erection of a new machine shop and factory building at Clinton and Mineral streets, to cost $30,000. The building will be of brick and steel construction, 2 stories high, 100 by 100 feet in size, and will permit the output to be doubled. At the head of the company is Frank J. Edwards, president of the Kissel Kar Co., of Milwaukee, and the Edwards Motor Car Co., Milwaukee agent for the Dodge.

New Ford Plants—The Ford Motor Co., Detroit, Mich., is planning to build an assembling plant in San Diego, Cal. It has also announced a $500,000 plant for Louisville, Ky. An architect from Detroit was in that city recently to determine the plans for a new assembly plant which is to be erected on the property of the concern at Third street and the L. & N. railroad crossing. The new structure will be four stories in height and will be similar to Ford assembly plants in other cities. It is planned to have the new building ready for occupancy when the local branch, now located at 931 South 3d street, proves inadequate for the growing business of the company in that territory.

Sphinx Plant Busy—Operations at the plant of the Sphinx Motor Car Co., York, Pa., are being gradually increased and scores of agencies, who will handle the new car, are being booked throughout the different parts of the country. It was stated by a member of the company that the combined contracts for 2,000 cars approximates $1,000,000 worth of business. The several departments of the factory are being increased and by the first of the year will be operated to their fullest capacity. The transfer of the plant, formerly occupied by the Hart-Kraft Motor Car Co., from the receiver, Donald H. Yost, to Howard Rohrer, M. G. Hollis and G. C. Aumen, of the Sphinx company, was entered this week in the office of the recorder of deeds.

The Automobile Calendar

Jan. 2-9 .... New York City, Annual Automobile Show, Grand Central Palace.
Jan. 2-9 .... New York City, Automobile Salon, Grand Ball Room of Astor Hotel, Automobile Importers' Alliance, E. Lascaris, Pres.
Jan. 3-10 .... Buenos-Aires, Argentina, Grand Prize of Argentina.
Jan. 5-7 .... New York City, Engineering Societies' Bldg., Winter Meeting Society of Automobile Engineers.
Jan. 8-14 .... Milwaukee, Wis., Show—Auditorium, Milwaukee Auto. Dealers' Assn.
Jan. 8-14 .... Kansas City, Mo., Show.
Jan. 9 .... San Diego, Cal., Road Race.
Jan. 9-16 .... Philadelphia Show, Metropolitan Bldg., Philadelphia Auto. Trade Assn.
Jan. 16 .... Detroit, Mich., Show.
Jan. 16-23 .... Cleveland, O., Show., Cleveland Automobile Show Co., F. H. Caley, Mgr.
Jan. 20-28 .... Lancaster, Pa., Hiemenz Auditorium.
Jan. 23-30 .... Montreal, Que., Show, Allen Line Liverpool Bldgs., Montreal Automobile Trade Assn., T. C. Kirby, Mgr.
Jan. 23-30 .... Chicago, Ill., Automobile Show, Coliseum and First Regiment Armory.
Jan. 25-30 .... Fall River, Mass., Show.
Jan. 25-30 .... Buffalo, N. Y., Show, Broadway Auditorium, Buffalo Automobile Dealers' Assn.
Jan. 30-Feb. 6 .... Columbus, O., Show, Memorial Hall, Columbus Auto Club and Columbus Auto. Trades Assn.
Jan. 30-Feb. 6 .... Minneapolis, Minn., Show, National Guard Armory, Minneapolis Automobile Trade Assn.
Feb .... Portland, Ore., Show, Portland Auto Trade Assn.
Feb .... Toledo, O., Show, Toledo Auto Show Co.
Feb. 1-6 .... Louisville, Ky., Show, Louisville Auto. Dealers' Assn., First Regiment Armory.
Feb. 2-7 .... Kalamazoo, Mich., Show, Armory.
Feb. 15-20 .... Grand Rapids, Mich., Show, Klingman Furniture Exposition Bldg., Grand Rapids *Herald;* C. L. Merriman.
Feb. 15-20 .... Omaha, Neb., Show, Auditorium, C. G. Powell.
Feb. 15-20 .... Bridgeport, Conn., Show, State Armory; B. B. Sterber.
Feb. 22 .... San Francisco, Cal., Vanderbilt Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.
Feb. 23-27 .... Ft. Dodge, Ia., Show, Armory, C. W. Tremain, Sec.
Feb. 23-27 .... Syracuse, N. Y., Show, Syracuse Auto Dealers' Assn.; H. T. Gardner, Mgr.
Feb. 27 .... San Francisco, Cal., Panama-Pacific Exposition, Grand Prize Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.
Mar. 6-13 .... Boston, Mass., Show, Mechanics Bldg., Boston Auto Dealers Assn., Boston Commercial Motor Veh. Assn.
Mar. 9-15 .... Des Moines, Ia., Show, C. G. Van Vliet.
Mar. 14 .... San Francisco, Cal., Panama-Pacific Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.
April .... Calumet, Mich., Show, Coliseum.
May 17-18 .... Boston, Mass., A. A. A. Annual Meeting.
May 29 .... Indianapolis, Ind., 500-Mile Race, Indianapolis Motor Speedway.
June 9 .... Galesburg, Ill., Two-mile Track Meet.
June 16 .... Chicago, Ill., Speedway, 500-Mile Race, Speedway Park Assn.
June 25 .... Sioux City, Ia., Track Meet.
July 4 .... Tacoma, Wash., Road Race.
Aug. 20-21 .... Elgin, Ill., Road Race.
Sept. 20-25 ...... San Francisco, Cal., International Engineering Congress.

The Week in  the Industry

Motor Men in New Roles

PULCHER President Wolverine Club—Martin L. Pulcher, vice-president and general manager of the Federal Motor Truck Co., Detroit, Mich., was elected unanimously as president of the Wolverine Automobile Club, at a meeting of the board of directors.

Petersilge Manager Standard Motor Truck—Emil Petersilge has become manager of the Standard Motor Truck Sales Co., Cleveland, O.

Belden Minneapolis Club Pres.—G. K. Belden was re-elected president of the Automobile Club of Minneapolis. All other officers were renamed.

Hamburg Heads Newark Club—A. V. Hamburg was elected president of the Automobile Club of Essex County, Newark, N. J. A. S. Cole was elected treasurer.

Hoopengarner Resigns from Swinehart—E. O. Hoopengarner, for 10 years branch manager in New York City for the Swinehart Tire & Rubber Co., has resigned. He has not stated his future plans.

Walton Resigns—E. A. Walton, during the last 3 years advertising manager of the Timken-Detroit Axle Co., Detroit, Mich., has resigned to return to the Burroughs Adding Machine Co., in the same position.

Tooker Advertising and Sales Manager—The American Bronze Co., Berwyn, Pa., maker of "Non-Gran" bearing bronze, announce the promotion of Marc L. Tooker to the head of its advertising and sales department.

Frampton Sales Manager—G. O. Frampton has been appointed by Cooper, the tire man, as general sales manager of the Cooper agencies at Cincinnati, Dayton, Columbus, O., Indianapolis, Ind., Nashville, Tenn., Knoxville, and Chattanooga, Tenn.

Stevens Makes a Change—H. E. Stevens has been appointed manager of the used car department of the New England branch of the Locomobile Co., Boston, Mass., following 9 years' service at the company's branch in New York City.

Kroh Gets New Appointment—Henry A. Kroh, who has been in the Boston motor field for some years, has been appointed New England representative for the Continental Asbestos Co., with headquarters at 171 Huntington avenue, Boston, Mass.

Kinnaird Columbus Club President—The annual election of the Columbus Automobile Club, Columbus, O., which was held December 14, resulted as follows: C. M. Kinnaird, president; Walter A. Pfeifer, first vice-president; C. Edward Born, treasurer, and Forest H. Tharpe, secretary.

Anderson and Brubaker Exchange Positions—A. R. Anderson has been appointed St. Louis manager of the International Harvester Co., St. Louis, Mo. He succeeded H. L. Brubaker who takes charge of the company's branch in Madison, Wis., where Mr. Anderson formerly held forth.

Changes in Boston Studebaker—H. T. Myers, for some years manager of the wholesale branch of the Studebaker Corp., Boston, Mass., has been promoted to have charge of the commercial car sales at the factory and G. N. Jordan, traveling sales representative in New England, has been appointed New England branch manager.

Carmichael Heads Star Rubber—With the reorganization of the Star Rubber Co., Akron, O., its new charter shows a capitalization of $200,000. The newly-elected officers are: President, G. W. Carmichael; vice-president, J. W. Miller; W. E. Wright, treasurer and secretary and general manager, E. M. Caldwell. G. E. Hall was elected sales manager.

Case Superintendent Resigns—J. C. Peil, superintendent of the molding department of the South Works of the J. I. Case Threshing Machine Co., Racine, Wis., and previously for 16 years superintendent of the foundries of the Pierce Motor Co., Racine, now part of the Case interests, has resigned to become superintendent of the foundry of the Maxwell Motor Co. at Dayton, O.

—

Garage and Dealers' Field

Sheboygan Has New Co.—The Auto Service Co., Sheboygan, Wis., has been organized by F. F. Fuller and A. A. Freund to give repair service on all makes of cars with a full line of Ford parts.

N. Y. Eisemann Moves—The Eisemann Magneto Co. has leased large offices and repair rooms in the Chandler building, 245 West 55th Street, New York City, and has given up its other branch at 123 West 52d street.

Agent for Winona Radialite Device—The Washington state distributing agency for the Winona Radialite device has been placed with J. H. Mudie, of 750 Central Bldg., Seattle Wash. The Winona product is a device that automatically turns the headlights of a motor car.

Cincinnati Winton Moves—The Cincinnati agency of the Winton Six has moved from its former location on West 7th street to 2812 May street, Walnut Hills. The new location, which is near one of the most beautiful residence sections in the suburbs, was formerly the sales room of the Eddy Automobile Co.

Reo Agents Have Dinner—All the New England agents for Reo cars, comprising about sixty, had their annual dinner at the Hotel Oxford, Boston, Mass., last week as the guests of James M. Linscott, New England distributor, and they were addressed by J. C. Brandimore and H. G. Etabler, two of the factory officials from Lansing, Mich.

Overland Dealers Meet—The annual banquet of the Overland dealers identified with the Connell & McKone Company, Eastern Massachusetts distributors, was held last week at the Boston Athletic Association, with nearly 50 dealers present. William J. Connell was toastmaster. Col. Isaac Kinsey and Mr. Van Beaver, foreign factory man, represented the Overland Company as special guests.

Milwaukee Adds Ford Accessory Branches—Milwaukee's list of motor supply branches handling Ford accessories and supplies exclusively has been increased by two by the establishment of a Ford branch of the Auto Mart at 813 Grand avenue, and the J. J. Dougherty Co. at 803 Grand avenue. Some time ago the Auto Supply Co., 127 Second street, opened an exclusive Ford supply store at 140 Eighth street, directly opposite the new Milwaukee branch of the Ford Motor Co. All of the new Ford supply stores are within a block of the new Ford branch.

International Cyclecar Office Moved—The sales manager's office of International Cycle Car and Accessories Co. has been removed from Chicago to the factory of Woods Mobilette Co., Harvey, Ill. All matters pertaining to dealers' contracts, car shipments and orders for Woods Mobilette parts and equipment will be cared for at the office at Harvey, Ill., which is in charge of O. R. Wolfe, sales manager, and J. C. Long secretary and treasurer of the company. The executive offices of International Cycle-Car and Accessories Company will be retained as formerly at 1109 Security Bldg., Chicago, and the show room and local sales room at 1509 Michigan Boulevard, Chicago.

Engineering Students Visit Jeffery Plant—A washing machine for laundering oily cotton waste was one of many money-saving appliances that made a profound impression on a party of engineering students from the University of Kansas when they visited the Jeffery automobile works recently. The students were in charge of Dean P. F. Walker, of the mechanical engineering department, and were visiting places of technical interest in and around Chicago. The tour included the Western Electric Company's plant at Hawthorne, Ill., the generating and sub-stations of the Commonwealth Edison Company at Chicago, and the automobile factory of The Thomas B. Jeffery Co., Kenosha, Wis. J. W. DeCou, in an impromptu speech, told how waste of all kinds has been avoided in the manufacture of Jeffery pleasure cars and motor trucks. Thus the oily waste is now laundered, much of the oil is retrieved, and the consumption of waste has been cut from over 1.000 pounds to less than 100 pounds a week. The waste is now used over again many times before it has to be thrown away. Formerly, the cost of small tools, such as taps, reamers, drills, files, etc., used to reach a staggering total. By the aid of efficiency ideas, this cost has been cut 60 per cent. For instance, the installation of a file-cutting machine, by which the worn files are resharpened instead of being thrown away, has turned a heavy liability almost into an asset.

Recent Incorporations in the Automobile Field

Canada

OTTAWA—Superior Tubes and Accessories, Ltd.; capital, $300,000; manufacture accessories. Incorporators: W. A. J. Case, J. B. Taylor, C. G. Lynch, all of Toronto.

TORONTO—Anglo-Canadian Motor Sales Co.; capital, $50,000; automobile manufacturer. Incorporators: A. G. Browning, 6 Adelaide, east, Toronto; G. E. Buchanan and others.

Colorado

DENVER—Denver Ford Starter Co.; capital, $50,000; manufacture of Ford and Metz starters. Incorporators: C. Miercort, A. A. Carnine.

Connecticut

HARTFORD—Charter Oak Motor Car Co.; capital, $20,000; dealer. Incorporators: Frank Zimmerman, E. H. Harris, F. W. Lycett, of Hartford.

Delaware

DOVER—Penn Rubber Traffic Co.; capital, $150,000; manufacture and sale of automobile tires and inner tubes. Incorporators: W. Boyd, W. I. N. Lofland, W. F. P. Lofland.

WILMINGTON—Hester Tire & Rubber Co.; capital, $300,000; tire manufacture. Incorporators: B. H. Friel, L. A. Brownhill, G. H. Purcell, all of Wilmington.

WILMINGTON—Motor Car Repair Shop; capital, $25,000. Incorporators: E. E. McDaniel, R. C. Pancoast, W. S. Hilles.

WILMINGTON—Pneumatic-Hub-Tire-Wheel Co.; capital, $500,000; manufacturer of wheels and tires. Incorporators: G. J. Lampton, N. M. Rowland, L. C. Evans, Louisville, Ky.

WILMINGTON—Sterling Motor Car Co.; capital, $10,000; manufacturer and dealer in automobiles. Incorporators: H. E. Latter, W. J. Maloney, O. J. Reichard.

Georgia

ATLANTA—Tatum Carbureter Co.; capital, $10,000; manufacturer. Incorporators: F. C. Myers, I. I. Tatum.

Illinois

ANNA—Anna Machine Shop & Garage Co.; capital, $5,000. Incorporators: R. W. Hynes, H. P. Sealey, J. P. Hynes, H. W. Smith.

CHICAGO—Adams Motor & Mfg. Co.; capital, $25,000; manufacturer in motors and machinery. Incorporators: W. E. Adams, H. W. Beaton, T. J. Mullen.

CHICAGO—Partin-Palmer Motor Car Co.; capital, $300,000; manufacturer and dealer. Incorporators: C. E. Heckler, Guy Guernsey, R. D. D'Autremont.

EDWARDSVILLE—American Standard Automobile Co.; capital, $100,000; parts and accessories. Incorporators: Peter Burnhardt, C. H. Gerling, Louis Kirsch.

MOLINE—Hager & Rank Automobile Co.; capital, $5,000; dealer. Incorporators: George Hager, Axel Sorling, R. W. Rank.

MOLINE—Moline Muffler Mfg. Co.; capital, $10,000; manufacturer. Incorporators: Ray Pupton, A. C. Walker, E. D. Jones.

PEORIA—Fashion Electric Garage; capital, $15,000. Incorporators: B. E. Adams, F. B. Kamarel, W. R. Bennett.

Indiana

GOODLAND—H. & D. Co.; capital, $10,000; dealer. Incorporators: A. P. Hawn, C. A. Doland, J. E. Hawn.

INDIANAPOLIS—Delaware Tire Sales Co.; capital, $1,500; dealer. Incorporators: C. M. Nesbit, W. T. Allen, C. L. Sawyer.

INDIANAPOLIS—Eclipse Mfg. Co.; capital, $50,000; spark plug manufacturer. Incorporators: W. S. Brown, W. S. Brown, Jr., B. M. Franklin.

INDIANAPOLIS—Indianapolis Garage Owners' Assn.; capital, $5,000. Incorporators: H. L. Bevington, A. W. Bowen, K. R. Vaught and others.

Kentucky

LOUISVILLE—Co-Operative Motor Car Co.; capital, $10,000; dealer. Incorporators: W. H. Reese, Herbert Stuber, W. R. Reese.

LOUISVILLE—Falls City Auto Co.; capital, $6,000; dealer. Incorporators: E. C. Pearson, S. J. McElliott, John Schildt, Henry Bosse.

Maine

PORTLAND—General Transit Co.; capital, $1,000,000; manufacturer in accessories and automobiles. Incorporators: E. E. Noble, E. V. Mann, all of Portland.

Massachusetts

BOSTON—Hood Tire Co.; capital, $20,000; deal in any kind of tires, rims and wheel equipment for automobiles. Incorporators: E. I. Aldrich, H. C. Mason, H. E. Rose, Robert Muir, C. W. Dailey, Jr.

Michigan

DETROIT—Dewesee Auto Safety Signal Co.; capital, $1,500. Incorporators: A. A. and I. P. Gottfield, Charles Edison, Charles Young.

DETROIT—National Electric Starter Co.; capital, $1,000; to market Ford starters built by Disco Electric Starter Co. Incorporators: M. B. and E. K. Sulzberger, J. S. Folz.

LANSING—Reliance Service & Supply Co.; capital, $3,000; accessories. Incorporators: E. L. Dunn, C. L. Winsor, M. B. Lipsitz.

Missouri

KANSAS CITY—Western Auto Supply Co.; capital, $20,000; dealer. Incorporators: George Pepperdine, Lena Pepperdine, E. R. Baker.

ST. LOUIS—St. Louis Welding Co.; capital, $150,000; to manufacture automobile wheel rims and do general metal welding, forging, machine and foundry business. Incorporators: Leo Ganahl, G. Becherer.

North Carolina

FAYETTEVILLE—Armfield-Percival Motor Co.; capital, $10,000; dealer. Incorporators: E. W. Percival, Jr., M. D. and D. F. Armfield.

New Jersey

PLAINFIELD—Queen City Auto Co.; capital, $30,000; dealer. Incorporators: F. Endress, F. Waller, L. Endress.

New York

BROOKLYN—Jack London Motor Car Service; capital, $500; dealer. Incorporators: H. L. Delatour, L. M. Denham, R. H. Sternberg, 315 Snediker avenue, Brooklyn.

BROOKLYN—Jefferson Automobile Co.; capital, $1,000; dealer. Incorporators: J. R. Howlett, 265 Jefferson avenue, Brooklyn; T. J. Howlett, C. E. Fiske.

BROOKLYN—Kestler Auto Service; capital, $5,000; dealer. Incorporators: Richard Kestler, Lawrence Kestler, 167 Clymer street, Bronx, New York City.

FAR ROCKAWAY—Traver Puncture Proof Tire Co.; capital, $400,000; tire manufacturer. Incorporators: Gustav Koenig, 10 Mott avenue, Far Rockaway; P. C. Traver, J. J. Higgins.

FREDONIA—Fredonia Garage Co.; capital, $5,000. Incorporators: Frank Apgar, Robert Forster, both of Fredonia, and Henry Lewis, Buffalo.

MT. VERNON—Albert Garage; capital, $10,000. Incorporators: P. E. Hendrick, M. C. Hendrick, F. C. Hendrick.

UTICA—Utica Mitchell Motor Car Co.; capital, $1,000; dealer. Incorporators: Isaac Denosky, Ida Denosky, J. W. Seton, all of Utica.

WALTON—H. S. Wakeman Co.; capital, $3,000; dealer. Incorporators: H. S. Wakeman, M. T. Smith, W. G. Smith, all of Walton, N. Y.

New York City

Armored Motor Car Corp.; capital, $6,000; armored automobile manufacturer. Incorporators: J. H. Allen, R. J. Baulsir, R. E. Rogers, all of 2 Rector street, New York City.

Automobile & Machine Spring Co.; capital, $10,000; automobile supplies, sundries and machinery. Incorporators: Ida and Ely Bramson, Morris Kleinburg.

C. S. and R. Co.; capital, $50,000; to manufacture motors, automobiles, etc. Incorporators: F. T. Harbach, 3681 Broadway, New York City; J. H. Pease, 549 2d avenue, Long Island City; F. W. Ritter.

Cochran's Garage; capital, $1,000. Incorporators: Julius Spalla, Louis Spalla, 151 Brook avenue, Bronx; John Spalla.

Cherokee Garage Co.; capital, $10,000. Incorporators: J. F. Fay, 104 E. 117th street, New York City; James Fay, F. Wengraf.

Federal Body Co.; capital, $1,000; automobile bodies. Incorporators: O. D. Shonnard, 246 Lenox avenue, New York City; S. Goldblatt, J. A. Cameron.

Greater New York Garage Co.; capital, $5,000. Incorporators: A. J. Beers, H. C. and J. T. Owens, 3647 Broadway.

Grand Concourse Service Co.; capital, $1,000; dealer. Incorporators: J. M. Ireland, M. A. Ireland, Caroline Haffen, all of 2505 Creston avenue, Bronx, New York City.

Globe Steel Products Corp.; capital, $5,000; ball bearings and automobile parts. Incorporators: C. F. Suitemeyer, J. R. Quinn, Max Vieweger, all of 50 Church street, New York City.

Natlus Auto Renting Co.; capital, $5,000. Incorporators: S. I. Goldberg, M. M. and J. S. Davis, 605 W. 111th street.

United Supply Stores; capital, $5,000; accessory dealer. Incorporators: A. S. Stein, L. G. Duquet, A. W. Chatfield, 312 W. 52d street, New York City.

X Protectyre Co.; capital, $20,000; to manufacture tire protecting devices and other automobile accessories. Incorporators: Isidore Neustaedter, H. J. Rosenbloom, both of 63 Park row, New York City; Alfred Alexander.

Ohio

CINCINNATI—Ford Supply Shop Co.; capital, $5,000; parts manufacturers. Incorporators: Walter Pursell, Bruce Schoolfield, A. W. Kops, H. N. Smith, T. J. O'Neill.

CLEVELAND—Ford Tire & Tube Co.; capital, $10,000; tire manufacture. Incorporators: E. E. Rodd, C. V. Liggett, U. L. Henry, C. A. Levy, Lee Ulmer.

COLUMBUS—Fourth-Chestnut Auto Repair Co.; capital, $10,000; garage. Incorporators: J. F. Steele, J. L. Steele, C. A. Lusch, E. T. Lusch, F. M. McSweeney.

COLUMBUS—Remington Auto Sales Co.; capital, $10,000; dealer. Incorporators: C. M. Shira, Orrin Thacker, W. A. Jackson, W. E. Penrose, G. H. Mosier.

MIDDLETOWN—C. C. Fouts Co.; capital, $75,000; to manufacture metal garages. Incorporators: C. C. Fouts, C. B. Oglesby, Paul Fouts, A. A. Amler.

Pennsylvania

BURLINGTON—Gamble-Waggener Co.; capital, $25,000; general motor car and sporting goods business. Incorporators: J. N. Gamble and others.

SCRANTON—Scranton Automobile Co.; capital, $100,000; to manufacture and deal in automobiles and engines and accessories. Incorporators: H. R. Shaw, Tracy Prevost, L. G. Stark, all of Scranton.

PHILADELPHIA—Standard Tire & Rubber Co.; capital, $250,000; to buy, sell and deal in all kinds of articles used in the manufacture of automobiles. Incorporators: F. R. Hansell, G. C. Seymour, G. H. B. Martin, of Camden, N. J.

Texas

EL PASO—Lone Star Motor Co.; capital, $25,000. Incorporators: Frank T. Pickrell, E. G. Perry and L. J. Trotti.

PORT ARTHUR—Port Arthur Garage; capital, $3,000. Incorporators: T. P. Smith, Albert Perkins and T. E. Linn.

Virginia

CLIFTON FORGE—Interstate Garage; capital, $1,000 to $5,000; motor car business. Incorporators: Eugene Mathews and L. W. Farrier, both of Clifton Forge.

DANVILLE—Crowell Auto Co.; capital, $30,000; dealer. Incorporators: A. J. Crowell, Charlotte, N. C.; A. B. Crowell.

RICHMOND—Service Sales Co.; capital, $1,000 to $10,000; motor cars. Incorporators: C. E. Rixford and E. J. Smith, both of Norfolk.

West Virginia

MANNINGTON—C. R. & J. I. Phillips; capital, $10,000; automobile dealers. Incorporators: C. R. Phillips, J. I. Phillips, Mary Phillips, Ortha Phillips, Laura McCrea, all of Mannington.

Washington

BELLINGHAM—Bay City Motor Car Co.; capital, $20,000; motor cars. Incorporators: W. A. Knight, Arthur Burgess and C. E. Abrams.

NORTH YAKIMA—Service Garage & Supply Co.; capital, $4,000. Incorporators: W. C. L. Halsey, K. M. Woods.

SPOKANE—Spokane Cycle & Auto Supply Co.; capital, $125,000. Incorporators: J. D. Alexander, H. A. McKellar and J. B. McKenzie.

Wisconsin

EAU CLAIRE—Taylor Motor Car Co.; capital, $5,000; to deal in motor cars and accessories, conduct a garage and repair shop, etc. Incorporators J. A. Taylor, F. N. Ferguson, Frank H. Stillman and Alexander McDonnell.

HORICON—Horicon Truck Co.; capital, $100,000; to manufacture commercial motor vehicles. Incorporators: Mackie Wells, B. M. Tallmadge and John A. Dietrich.

MADISON—Star Tire & Rubber Co.; capital, $5,000; general motor car supply business. Incorporators: John W. Mart, C. E. Mart and Minnie Mart.

MILWAUKEE—Edwards Motor Car Co.; capital, $10,000; to deal in motor cars. Incorporators: Frank J. Edwards, Arthur A. Mueller and Margaret Mollerus.

MILWAUKEE—Modern Stamping & Mfg. Co.; capital, $150,000; to manufacture tools, machinery, appliances and die castings, stampings, etc. Incorporators: J. P. Foley, A. C. Jorgenson and H. F. Friedrich.

MILWAUKEE—Wisconsin Garage Co.; capital, $20,000; to conduct a general motor vehicle business and operate a repair-shop and livery. Incorporators: George Ashley DeWitt, George A. Daly and Louis M. Kotecki.

MILWAUKEE—L. & H. Auto Sales Co.; capital, $10,000; deal in automobiles. Incorporators: L. E. Ehrhardt, H. E. Toelle, Benjamin Ross.

MILWAUKEE—Burgett & Co.; capital, $25,000; to deal in motor cars and operate a garage and service station. Incorporators: J. C. Coxe, W. G. Burgett and F. C. Durham.

MILWAUKEE—DeWitt-Schank Motor Sales Co.; capital, $50,000; deal in automobiles. Incorporators: G. A. DeWitt, W. G. DeWitt, E. S. Schank.

ST. CLAIRE—Taylor Motor Car Co.; capital, $5,000; to deal in automobiles and operate a garage. Incorporators: J. A. Taylor, F. N. Ferguson, F. N. Stillman, Alexander McDonald.

CHANGES IN CAPITALIZATION

District of Columbia

WASHINGTON—Matheson Motor Car Co. to Premier Motor Sales Co.

Michigan

DETROIT—Scripps-Booth Co., from $50,000 to $150,000.

Missouri

ST. LOUIS—Velie Motor Co., from $10,000 to $20,000.

Ohio

EAST PALESTINE—East Palestine Rubber Co., from $150,000 to $500,000.

NEW PHILADELPHIA—Ohio Sales Co., from $20,000 to $50,000.

Washington

WILBUR—Enterprise Garage Co.; capital, $8,000; to operate a garage. Incorporators: E. L. Farnsworth, A. Alexander, R. H. Schriber and Bernt Pedersen.

Wisconsin

RACINE—Racine Rubber Co. to $1,500,000.

Accessories for the Automobilist

COMBS Spring Tire—Presley S. Combs, Seattle, Wash., is inventor of a new type of tire, Fig. 1, that operates on a cantilever spring principle. The tire in reality is a demountable rim to which are securely fastened forty-eight springs of the cantilever type. At the ends of these springs are twenty-four blocks, faced with rubber to a thickness of one and a half inches. Two springs are attached to each block, one at each end. The weight of the car presses down on the springs, and in that matter produces the resiliency of a pneumatic, it is claimed. In addition to possessing long wearing qualities, the maker claims it is positively immune from skidding. It has been tried out on trucks and a series of tests are being made on pleasure cars.

The device is known as the Combs tire and will be manufactured by the Combs Auto Tire Company, temporary offices of which are at 2005 Alaska Building.

Revivo Storage Battery—A lead battery, Fig. 2, which uses a semi-liquid electrolyte is the Revivo, made by a new concern, the Kentucky Revivo Battery Co., Louisville, Ky.

The grids or plates are made very much as are other lead plates but the difference between this and other storage batteries consists in the formation and character of the electrolyte, which ordinarily consists of sulphuric acid in solution at about 1,280 specific gravity, while that used in the Revivo battery consists of a solution of sulphuric acid, a solution of sodium silicate and asbestos, in proportions to form a jelly, the asbestos absorbing and holding the solutions, and this is placed in the cells, filling the space between the plates completely. As its name indicates, it revives quickly and can be run down to 1.5 volts or less, it is said.

There are many points claimed for the Revivo dry storage batteries for vehicle propulsion over other types. It is claimed they will not buckle, corrode, scale, be injured by short circuit, spill or slop over, destroy wood work, be injured by heat or cold and require no attention other than recharging, and that they can be charged the same as a wet battery, used in any position, and will give full electro-motive force from the start, will stand overcharging without injury, complete discharge without injury, stand freezing, remain active if cells are broken, and show long life.

Sampson Repair Plug—Repairing punctures in tubes by mechanical means is the advantage offered by the Sampson Repair plug made by Stevens & Co., 375 Broadway, New York City. This plug differs from the ordinary brass plug in that it is made of soft rubber with a metal core to reinforce it. The soft rubber prevents chafing and cutting of the tube. The plug consists of two flat disks that are screwed together clamping the tube between them. The projecting part of the screw is then cut off with a file.

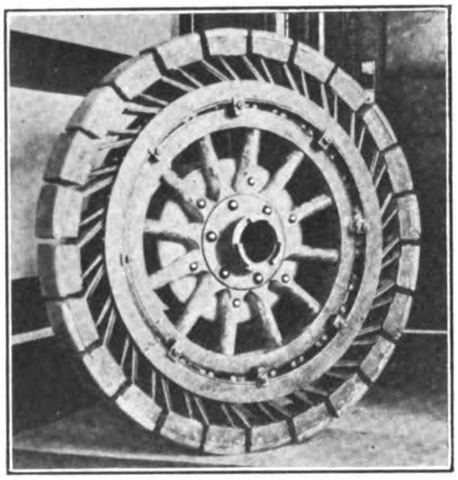


Fig. 1—Combs cantilever type spring tire

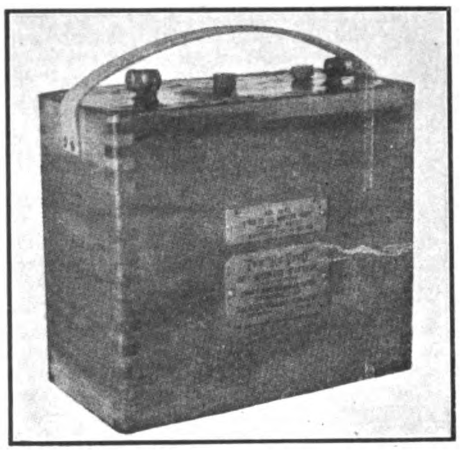

Fig. 2—Revivo storage battery

Newtype Mirror Search Light—The combination of the Newtype electric search light and a diminishing light mirror serves a double purpose in allowing the driver the use of a light where and when he wants it at night and in the day time the use of a regular mirror for seeing vehicles approaching from the rear.

Fig. 3 illustrates the mechanism of this device which comes complete with all necessary brackets and wiring attachments to the lamp so the lamp may be installed on the car in a few minutes time. The switch is in the handle of the lamp so that the driver can turn this light off and on as desired without interfering with the other lights. By wiring this lamp direct to the battery an emergency lamp is made which can be used in case the other lights go out from wire trouble and fuses blowing out.

This lamp is manufactured by the Wood Mfg. Co., Fairfield, Conn.

Dover Emergency Gasoline Tank—A one-gallon tank for storing gasoline for emergency use is made by the Dover Stamping & Mfg. Co., Cambridge, Mass. It measures 8.5 by 3 by 12 inches, is made of steel and is protected by a wood casing. The price is $1.

Rotobrush—This device consists of a high-speed revolving brush propelled by a water-motor. The brush is flooded with water and therefore it will quickly remove dirt from any surface. The Rotobrush is made of aluminum and sells for $10. It is manufactured by the Edgar Mfg. Co., 104 Hanover street, Boston, Mass.

Safeguard Mechanical Hand Horn—A hand-operated horn for $5 is made by the Duplex Electric Mfg. Co., Pittsburgh, Pa. It is enameled black and it is stated that all metal parts are made from fine heat-treated tool steel and the diaphragm from a fine grade of Swedish metal.

Keep Kool Ventilator—The Gahm Mfg. Co., Streator, Ill., has brought out a ventilator for Ford cars that allows the lower end of the windshield to be moved back so that a current of air may be supplied to the front compartment. The ventilator is easily attachable and is made in triangular shape, which makes it sufficiently strong and rigid for the most exacting service.

The adjustments can be slid forward and backward from the dashboard without loosening the adjustment which holds the windshield, so that there is no danger of the windshield slipping out of adjustment.

Freeman Self-Filling Grease Gun—A grease gun which may be simply and easily filled in a few seconds without soiling the hands is made by the Elmar Mfg. Co., Alameda, Cal.

To fill the gun, the nozzle cap is swung open and held back with the lever. Then the piston rod is drawn out its full length and while held here the handle is turned to the right until the piston rod engages the inner tube. The piston rod is pushed in again and the slotted inner tube will extend from the barrel. Then the inner tube is imbedded in the grease its full length. Turn the entire gun to the right to cut out the load. Then the filled inner tube is drawn back into the barrel by

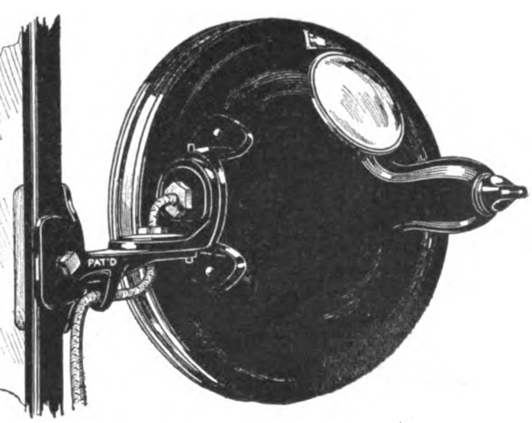

Fig. 3—Newtype mirror searchlight

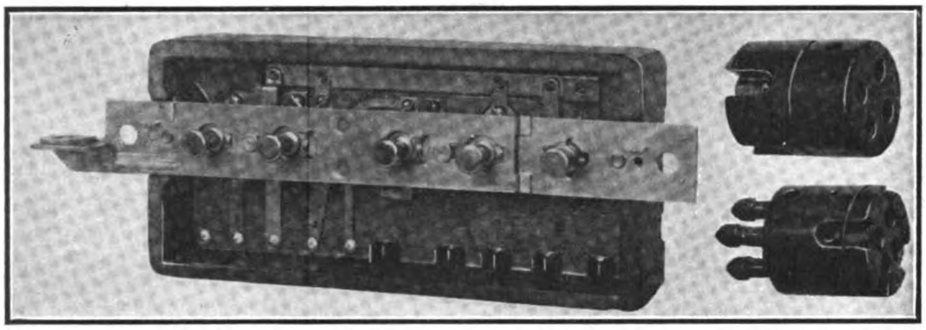

Fig. 4—Thermoplax and Pyroplax insulating materials to resist high temperatures

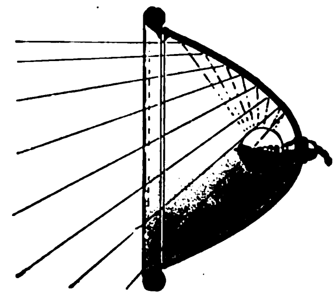

Fig. 5—Hick-Meyer deflector

pulling the piston rod out again. The nozzle cap is then closed.

The price is $2.

Hick-Meyer Deflector—A new non-glare headlight, Fig. 5, is made by the Hick-Meyer Deflector Co., Toledo, O., in which the light rays are never more than 4 feet above the ground. The light is more intense than can be produced by an ordinary lamp, it is claimed, for the reason that all the light is deflected forward and downward.

The deflector is made of special steel, shaped to fit snugly on the lower half of the light bulb, and has a mirror polish inside.

This has the effect of throwing all the light rays against the upper half of the lamp's parabolic reflector, from which they are sent forward and downward, in a safe and highly serviceable manner.

To the oncoming driver a lamp thus equipped has no glaring rays. The upper half seems well, but not dangerously illuminated while the lower half has only a faint glow.

Perfect Starter—The Perfect Starter, Fig. 6, is a one-unit device made in two sizes which operates as a motor or compressor and is placed under the hood. It is a four-cylinder machine with the cylinders arraigned V-shape. As a two-stage air compressor it will provide air at 300 pounds. The complete device is very simple; there is but one shut off valve in the entire system. The seat of this valve is of special design and it is stated, will not leak even after long service.

The small starter is 8.75 by 7.63 by 4.06 inches and it weighs 55 pounds with complete equipment. It is designed for the average car. For exceptionally large motors a starter weighing 75 pounds and measuring 11 by 9.38 by 5.13 inches is used.

The Perfect starter is made by the Motor-Compressor Co., 30 Halsey street, Newark, N. J.

Accessories for the Trade

GISHOLT Periodograph — This instrument automatically keeps track of each workman's time. It consists of a master clock, a panel board for the tickets and registers throughout the shop conveniently located, for the workmen to record the time on the job. In recording his time the workman simply puts his card into a slot in the nearest register and pulls a lever once. The time spent on each job is automatically recorded. The Periodograph does not operate during lunch hour or after hours, therefore only the actual working time is taken account of.

The instrument takes its name from the principle upon which the records are made. A unit of time, usually one-tenth

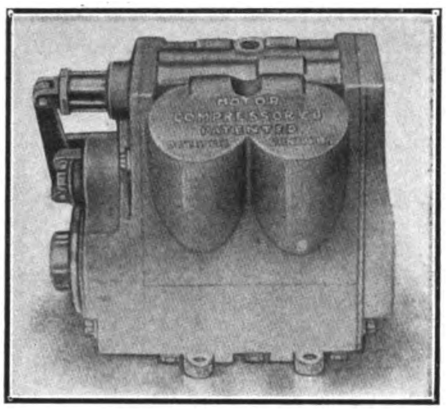

Fig. 6—Perfect starter and air-compressor with V cylinders

of an hour, is called a period, although the unit may be any fraction of an hour. These units are numbered or counted continuously throughout the working hours of the day, week or month, as desired. Distinctive overtime records are provided.

It is made by the Gisholt Machine Co., Madison, Wis.

Thermoplax and Pyroplax—Two composition insulation materials, Fig. 4, for electrical insulating work are made by the Cutler-Hammer Mfg. Co., Milwaukee, Wis.

Thermoplax is a black molded composition insulation which will resist heat up to 600 degrees Fahrenheit, and it is stated, will not warp, shrink, expand or soften when subjected to temperatures ranging from 30 degrees below zero to 600. It has a dielectric strength of 70 volts per mil and a cross-breaking strength of 1,100 pounds per square inch. It can be highly polished and may be moulded into any shape without difficulty.

Pyroplax has the same general characteristics but will resist temperatures up to 1,000, has a cross-breaking strength of 1,400 pounds and a dielectric strength of 60 volts per mil. It is made in two grades, white or plain, where intense heat is to be encountered, and brown or impregnated where a water-proof material is required.

Esterline Battery Charger—The Esterline company has perfected a dynamo, Fig. 7, suitable for charging both 6 and 12-volt batteries. The outfit is made up as nearly automatic as possible, so that it requires no attention on the part of the operator other than connecting up of the batteries and disconnecting them when they have been fully charged.

The dynamo is fitted with a pulley suitable for belting to a line shafting on an electric motor. It is fully enclosed to keep out dust and dirt and is fitted with ball bearings of large size running in oil.

The dynamos are furnished in two capacities, rated at 12 and 18 amperes respectively.

The switchboard is fitted with a zero center, nickel plated ammeter for showing the charging current; and an automatic switch for connecting the batteries to the generator and for immediately disconnecting them in case the generator should for any reason be shut down. Provision is also made on the board for connecting four batteries to the dynamo at one time.

The switchboard is 10 by 20 inches and is made for mounting on or near the wall. All permanent connections are made in the rear of the board and the battery connections on the front.

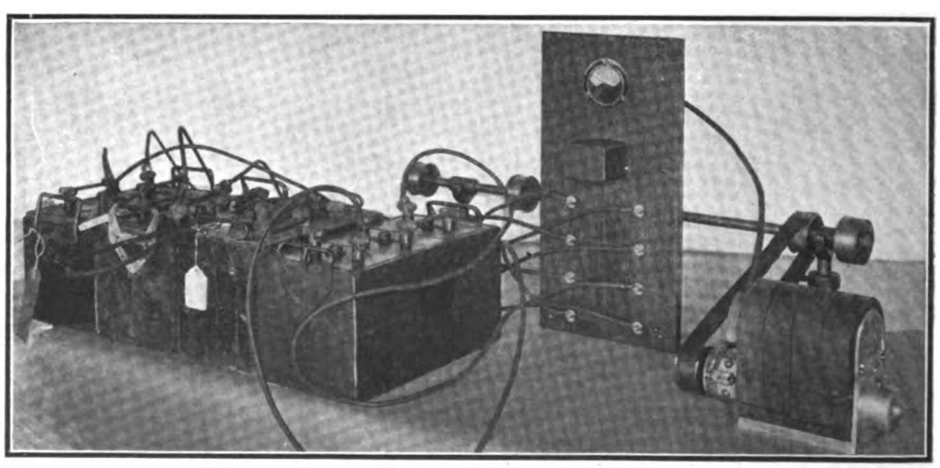

Fig. 7—Esterline charging generator suitable for charging 6 and 12-volt batteries. The generator is driven from a motor by a belt

1915—A 7-League Stride

Eight-Cylinder Motors—Sixes for Less Than $800—Vacuum Feed—Spiral Bevel Gears —Better Equipment—The Year's Milestones

SIXES for less than $800; eight-cylinder motors; block-cast, unit power plants; high stroke-bore ratios; spiral-bevel drive; vacuum-feed; cantilever springs; lower weights; smaller tire and maintenance expense are the giant strides in the automobile industry during 1914.

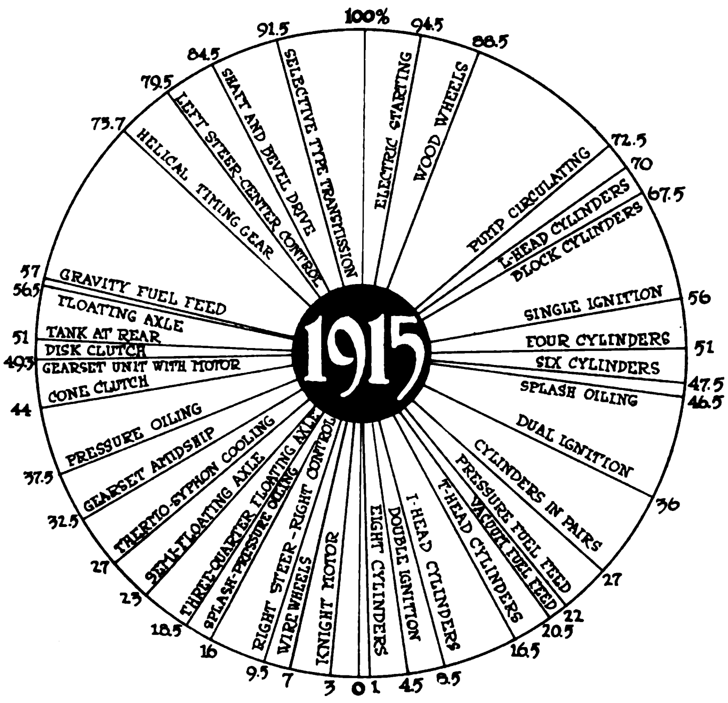
Cars are lower priced. A year ago the cheapest six was $1,500, now it is $750—a 50 per cent. reduction.

With the reduction in weight have come longer, lower lines. Cleanness of design has been typified in the rush to the standards of block design. Although S. A. E. horsepowers on the average are reduced, the growth of the high-speed, high-efficiency design has put our motors on a higher plane than ever before.

Better equipment is offered at the lower price. The average car of today sells for $2,005; lower than at any time in the history of the industry. Yet the car of today is more comfortable, easier riding and has far more to offer in the way of comforts for its passengers than ever before. The one-person top, cord tires, fine dash equipment, better control features, motor-driven tire pumps, and luxurious upholstery even on cars selling for below $1,000 are noteworthy features in development.

Bodies are handsomer. The clean moulded lines have developed during the year. Side lamps have been eliminated; battery boxes taken from the running boards. The introduction of vacuum feed and the removal of the tank from below the front seat has permitted lower lines. Prominent makers have increased the drop in the frames, heightening this effect. Electric starting and lighting is used on cars costing as low as $600.

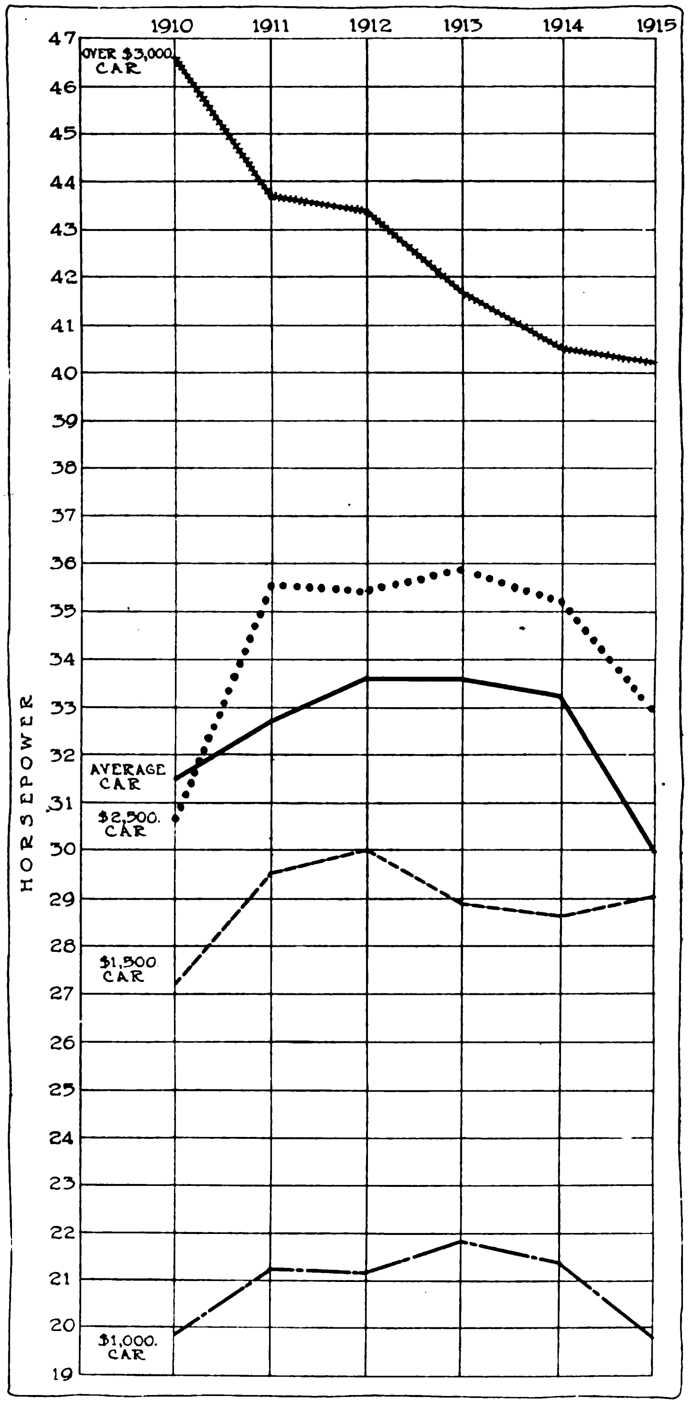
In numbers our automobile manufacturers are fewer than they were a year ago, and in fact the numbers have been annually growing fewer ever since 1911. We have now listed 119 manufacturers as against 133 in January 1914, 156 in 1913, 193 in 1912, 270 in 1911, and 239 in 1910. The year of 1911 was the zenith in the number of manufacturers.



THE 1915 CYCLE OF PROGRESS IN DESIGN
Nearly half our cars are sixes; 70 per cent. have L-head cylinders; 67.5 per cent. have the cylinders cast in block; vacuum fuel feed, unused a year ago, is now fitted on 20.5 per cent. of the cars; left steer and center control is used on 79.5 per cent., and helical timing gears on 73.7 per cent.

Fewer Chassis Models

The number of chassis models has had its rise and fall in the same proportion. In 1910 there were 364 chassis, in 1911, 393; in 1912, 381 and in the remaining 3 years to January, 1915, 339, 236 200. Although there are but 200 chassis offered by the manufacturers, there are 535 cars, an average of more than 2.5 car models to the chassis. The number of cars offered a year ago was 607. These cover all types of body and offer a broad choice



HORSEPOWER TRENDS FOR 5 YEARS

The average horsepower is lower now than a year ago. In the car at over $3,000 it has descended steadily. In the $2,500 car it has zigzagged for 5 years and similarly in the other price classes. It is now lower in every class except that of the $1,500 car

to the purchaser in size, price and important specifications.

Fifty-eight of our makers are listing but one chassis. In these, twenty-seven are selling cars below $1,250, twelve are selling cars between $1,250 and $1,999, eleven from $2,000 to $2,999 and eight at more than $3,000. These four price classifications cover the range of cars and, since the selling price must govern the allowable cost of manufacture, and hence, the whole groundwork of engineering design, it is purposed to study the trends in each of these classes independently. For convenience, we will call them the $1,000, $1,500, $2,500 and $4,000 cars.

Two reasons may be given for the increase in wheelbase length during the past year. The principal one is the increase in sixes. These, which have grown remarkable in numbers in the $1,500 class are universally longer than the fours which they have replaced. In other instances a longer wheelbase has been taken up in the body. The biggest increase was made by Hupmobile which is now 13 inches longer; the greater length being required by the larger motor and roomier body. Several other makers have increased the wheelbases 1 to 2 inches, the added space going into the body.

Wheelbase Has Increased

We have wavered between 121 and 122 inches alternately since 1912. In 1911 the average wheelbase was 114 inches and in 1910, 112 inches. The years of the biggest change in wheelbase were between 1910 and 1912 as in these 2 years it increased 9 inches, whereas, since that time it has only varied within the limits of 1 inch. The general average of all chassis is 122.2 inches, in 1914 it was 121 inches, for 1913 it was 122, the same as for 1915, and in 1912 it was the same as for the 1914 season.

The $1,000 car is only .37-inch longer than it was in 1914, but between 1913 and 1914 there was a gain of 4 inches; between 1912 and 1913 there was a loss of 1 inch. Thus in the low-priced cars also we find the years of doubt in length to be from 1912 to 1915, when the wavering of figures was between 103 and 107. As in the general average, the upward trend in wheelbase was in 1910 to 1912, when it rose from 96 to 104 inches.

The wheelbase of the $1,500 car has increased steadily during the last five years, reaching its highest point in 1915, 121.6 inches or a gain of 3 inches over 1914. From 1910 the growth of wheelbase was steady until last year when it was .5 inch less than in 1913. The figures are: 1910, 109 inches; 1911, 114 inches; 1912, 116 inches; 1913, 119 inches; and 1914, 118.5 inches.

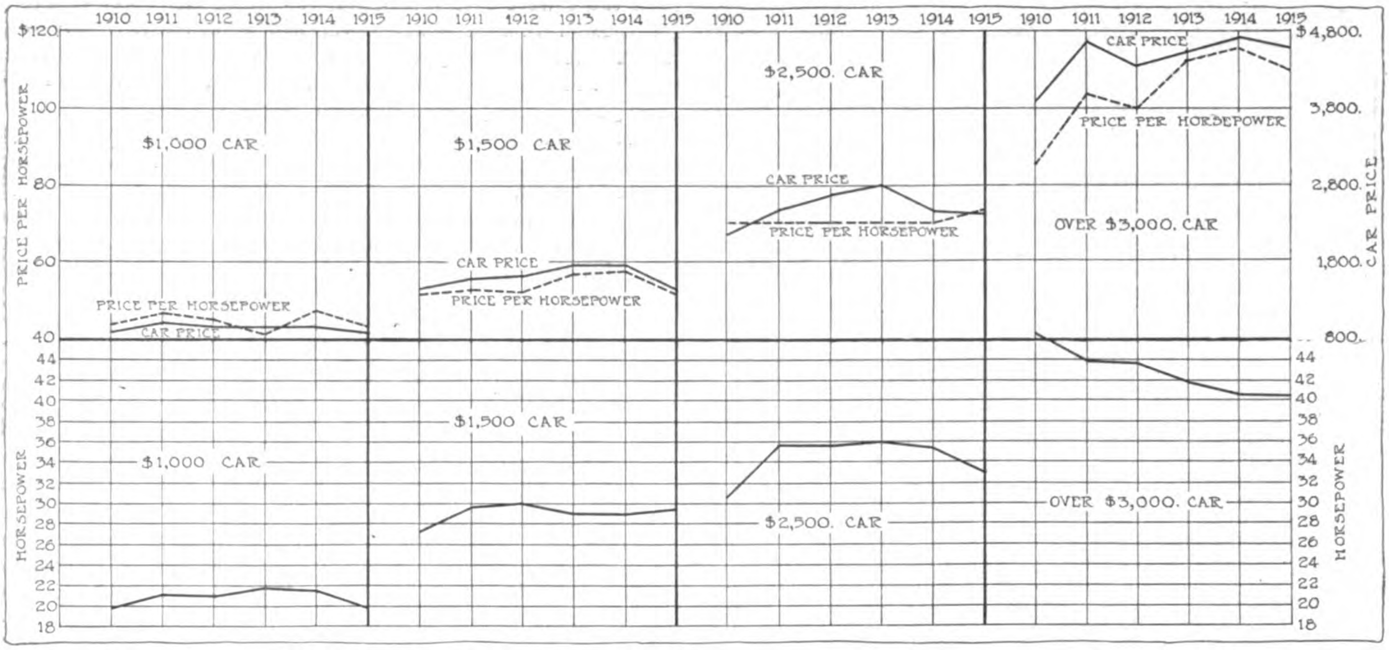
In analyzing the wheelbase trends in the $2,500 car during the past 5 years there have been two pronounced periods of lengthening, first when the average increased 6 inches between 1910 and 1911 and again between 1912 and 1913 when 7 inches were added. The first increase was due to the general movement to build longer cars for riding comfort and the second between 1912 and 1913 was due entirely to the six-cylinder movement. The increase from year to year is shown in the following figures: 1910, 113 inches; 1911, 119 inches; 1912, 120 inches; 1913, 127 inches; 1914, 125.8 inches; and 1915, 126.6 inches.

The wheelbase of the average car listing at over $3,000 has increased steadily for 5 years, jumping from an average of 124 inches in 1910 to 133.2 for 1915. In this period there has only been one perceptible increase, 5 inches, between 1911 and 1912, and since then it has steadily climbed up 1 inch per year. The 5-inch jump was due to the six-cylinder movement which in that year grew from practically zero to 44 per cent.

Tires Are Smaller

The increase in economy of the chassis while at the same time an increase in length has been made, indicates that steps must have been taken to lighten the weight and simplify the component parts. That this is so, is shown alone in the tire size, which is this season smaller than at any other time since 1911. It is now in the 1915 car 34 by 4 on the average chassis. For 1914 and 1913 the average tire size was 35 by 4.5. In 1912 it was 35 by 4. The tire size for 1910 and 1911 was 34 by 4 so that now we have come back to the tire size of 5 years ago. This was the day before the manufacturer fully equipped his car and it would now seem if unit tire weights are the same, that the added weight of electric equipment and the other comfort features throughout has been compensated for by the development of the other parts of the chassis.

Big changes in motor design have been made during 1914. Block castings have jumped to supremacy, sixes have still continued to gain, stroke-bore ratios have increased, L-head cylinders are now well in the lead, and bores are smaller and



CAR PRICE AND ITS RELATION TO HORSEPOWER

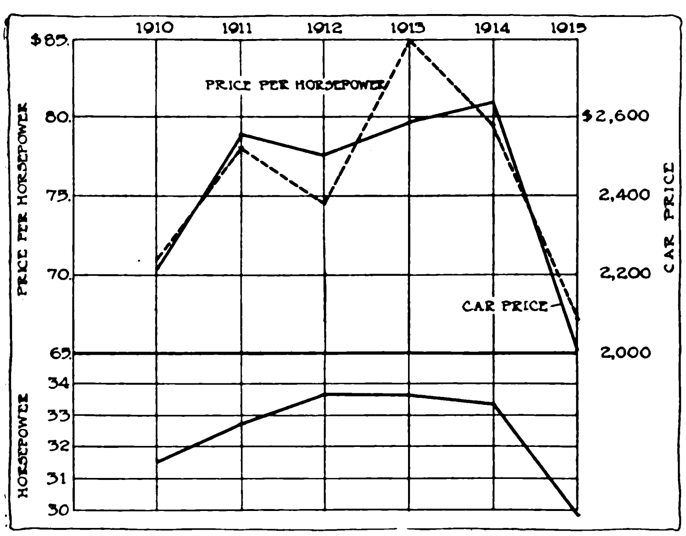
The price per horsepower in every class has been an uncertain factor for the last 5 years. Up to 1914 the trend was generally upward, the reason being that each year makers were compelled to charge more for the equipment that they added. For 1915 this has undergone a change, and now the unit price is lower than a year ago

strokes about the same length. In the motor auxiliaries mountings have been simplified, adjustment points are more accessible, carbureters are higher.

In the motor systems: cooling, ignition, lubrication and cranking, many detail improvements may be noted. Thermo-syphon is on the increase, pump circulation has dropped due tc the influx of low-priced cars using thermo-syphon. Air-cooling is only used by Franklin. The single ignition system is rapidly ascending the scale of popularity, displacing the dual. Pressure oiling is growing with the use of the high-speed motor and electric cranking and lighting systems are lighter, more efficiently connected, simpler and have better electrical characteristics than a year ago.

Average Horsepower Less

While chassis have universally been increasing in length since 1910, motor sizes have risen to their highest point in the years of 1912 and 1913 and are now on the descending scale.



PRICE DEFLECTION AND HORSEPOWER

Car selling price reached its zenith in 1914, after a steady upward trend since 1910, and yet the drop on the average car has been so great during the past year that for 1915 the average selling price is lower than at any time in the last 5 years

The trends of motor design are discussed under a separate head, but what manufacturers of cars are doing in a general way should be mentioned here.

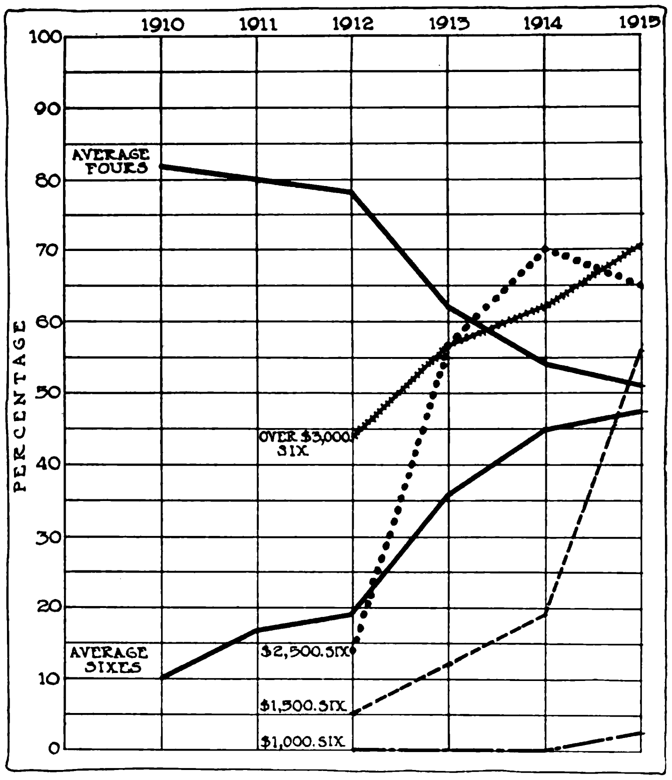
The highest average horsepower reached by all manufacturers is 33.6 and these figures held good for the years of 1912 and 1913. In the 2 years since then, it has fallen to 33.2 in 1914 and 29.97 for 1915. It would be expected that since the prices of cars are on the whole lower, the average horsepower of the cheaper cars would be more, but the contrary is true, and the only car which has risen in horsepower is that in the $1,500 class.

Horsepower figures for the $1,000 car show a rise from 1910 to 1913 of from 19.85 to 21.86; in 1914 the figure was 21.4 and in 1915 the drop has been accentuated by a fall to 19.78. In this price class the drop can be accounted for by the addition of the miniature car. A year ago, there were many cyclecars. These have passed and in their place we find the development of another class of car which may be known as the miniature. It is replete with many of the comfort features of the larger cars but it is small in size and has a motor with a bore which is in such examples as the Saxon six, the Grant six and in fours made by these two concerns and others such as Scripps-Booth, Remington, Rayfield, and Vixen under 3 inches. The examples of the two sixes, the Grant at $750 and the Saxon at $785, mark the commencement of a new era in motor characteristics in cars of this price.

Cars of $1,500 have an average of 29.01 S. A. E. horsepower for 1915 as compared to 28.6 for 1914. The reason is in the large increase in sixes in this price class. The highest point in horsepower in cars of this class was in 1912 when it was above 30, being 30.01. This was the culmination of a rise from 27.20 in 1910 to 29.53 in 1911.

In the $4,000 price class there has been practically no horsepower variation for 1914 and 1915. These figures being resepctively 40.50 and 40.22. Unlike in any other price class, the highest horsepower was in 1910 and since that time the curve of S. A. E. horsepower has shown a steady downward tendency, losing a little each year as will be noted from the chart.

The coming season marks the introduction of the six into the low-price field and Grant and Saxon are the pioneers. On the whole the six has gained ground, having risen from 45



NUMBER OF CYLINDERS

The six has been gaining ground steadily since 1910. The four has correspondingly fallen off in percentage and the curves are practically complementary. In the price classes the six has risen everywhere, being now even in the $1,000 class

per cent. in 1914 to 47.5 in 1915. The gains of the six through the various years will be discussed under motors, but in the different priced classes it may be mentioned here that it has gained everywhere except in cars selling for $2,500. The gain in the $1,500 class has been most marked. In 1914, but 19 per cent. of $1,500 cars were sixes, now more than half or a percentage of 55 are sixes. In 1912 the six was introduced into the $1,500-class in the same way that the six is now being introduced into the $1,000 class. It made its entrance with 5 per cent. and in 1913 this had risen to 12. Another 7 per cent. was gained in 1914, bringing it up to 19 per cent. This year has come the landslide and now there are but 40.2 per cent. which are fours and in addition to this the entering wedge of the eight has appeared. The eights are in the number of 4.1 per cent.

A drop of 5 per cent. in sixes has occurred from 1914 to 1915 in the $2,500 class. In 1914, 70 per cent. of all the $2,500 cars were sixes and 30 per cent. fours. This year the 1915 season opens with 65 per cent. sixes, 33.3 per cent. fours, and 1.7 per cent. eights. The drop in percentage of sixes in the $2,500 class is not due to a drop in popularity of the six, because if that were so it would be shown in the average figures for all classes. The number of makers of $2,500 cars, however, has dropped from 60 to 42 and as will be noted in the examples mentioned under the head of motors, a large number of the concerns which have been eliminated were manufacturers of sixes in this class.

Fewer Expensive Cars

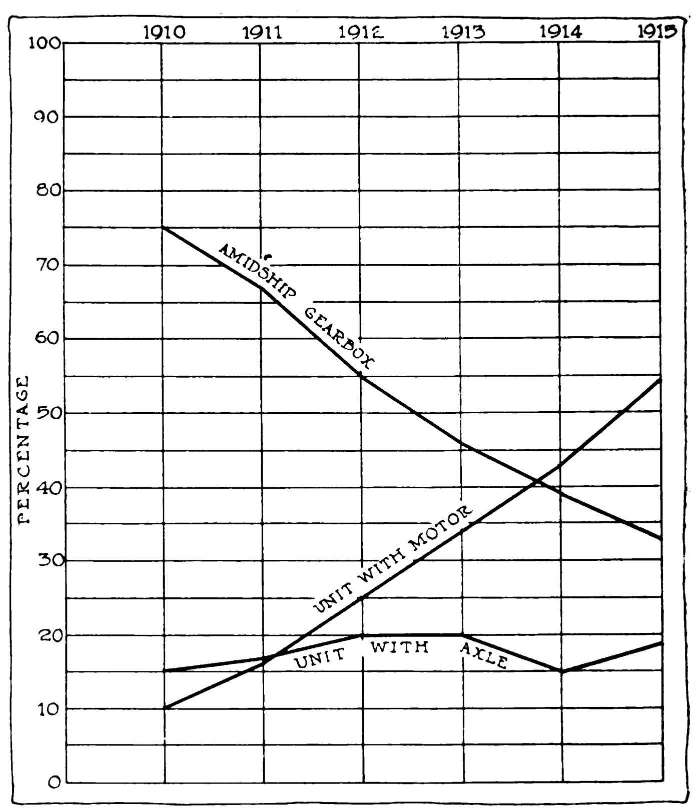
Among makers of expensive cars, the falling off in numbers has been greater than any other, but in spite of this the percentage of sixes has grown. It must be remembered that a large proportion of the cars listed in this price class are on chassis which would sell in a lower-priced class were they fitted with touring or roadster bodies. Sixes are used on 70.5 per cent. of the $4,000 cars. The rise since 1912 has been continued. In that year there were 44 per cent. using the six, in 1913 there were 57 and in 1914, 62. Thus the curve of sixes for cars of this class has never had a depression since the introduction of this type of motor. The eight is also in this class when equipped with the inclosed types of bodies. Percentage is not important however, being but 1.5.

Developments in the entire drive system do not show any radical change in the types of units used. The percentage of disk clutches is the same now as it was in 1911 and very little change has taken place during this lapse of time. The same may be said of cone clutches and working back through the gearbox, driveshaft and final drive, it is only in the rear axle and suspension that the changes are of great enough degree to attract more than passing attention. Yet throughout the entire transmission system, gains in efficiency have been made.

Disk Clutch in Majority

Only in 1 year, 1912, was the majority of cars equipped with a cone clutch, but the percentage of cone as compared with disk has always been close. In 1912 52 per cent. were equipped with cone clutches and 44 per cent. had disks. In 1915, 51 per cent. have disks and 44 per cent. cones. The difference between these figures and 100 per cent. is made up by the small percentage that use the expanding and contracting band type or that have no clutch at all, such as the Cartercar, Lambert and Metz with friction drive or the Owen with its electro-magnetic transmission.

Clutches in themselves have been improved. It must be remembered that the broad classification of disk clutches includes many minor types that differ quite widely in their use. The disk-in-oil with its many plates is not like the dry-plate type with its fewer plates or like the three-plate type which is clearly described by its name. The dry-plate clutch has gained in percentage over the disk-in-oil since 1910, but during the last 2 years has remained nearly stationary. Improvements in the engaging springs, making them gradual



GEARBOX LOCATION

Unit power plants have gone up steadily and amidship gearboxes have dropped steadily since 1910. The other classification, that of the axle unit, has zigzagged between 15 and 20 per cent. during the 5 years and yet eliminating slip which was the early enemy of the disk-in-oil clutch, have been consummated during the past 3 years. There has been a tendency towards dividing the clutch spring into three parts, making a more uniform distribution of the spring load.

Little Change in Cones

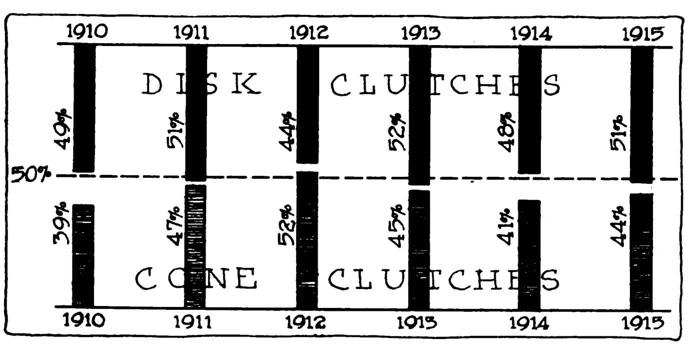
In cone clutches little change has been made during the year and where it has been made it is in the direction of easy engagement or accessibility. Marmon, for instance, has introduced the circular disk spring beneath leather, and Empire has improved the assembly so that the average driver may adjust the tension on the clutch spring without trouble. Diameters of clutch cones have not changed on the average installation, but the faces are inclined to be slightly wider, giving a greater bearing surface for the leather. The pressed steel cone is in the ascendancy. Cadillac has changed from cone to disk and McFarlan from disk to cone.

The expanding band clutch has fallen off since 1914, but the difference in percentage is very slight being .5 as compared to 3 per cent. Peerless continues to use it on one model and is the last remaining devotee of this design. The contracting band is still used on 4.5 per cent. and has lost but .5 per cent. since 1914, when it was higher than at any time of which there is previous record. In 1910 3 per cent. used contracting-band clutches and 6 per cent. used the expanding band. Percentage of contracting-band dropped to 1 per cent. for 1911 and 1912 and 2 per cent. in 1913. The makers who employ the contracting-band clutch are Apperson and Haynes.

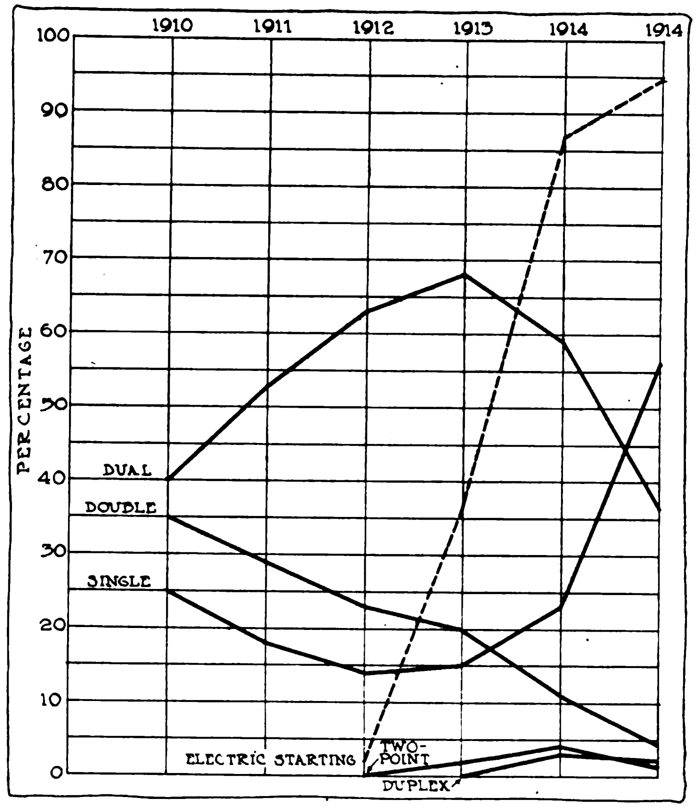
Center Control Aids Simplicity

In gearset design no radical changes can be said to have been made during the past year. With the introduction of center control on the large percentage of our cars it has been possible to greatly simplify the linkage which connects the gearshifting lever to the gearbox. On center control cars it is now common practice to mount this lever directly on the gearbox cover and thus avoid the bell cranks and shafts which were necessary with the side levers. Gear faces are almost universally wider, although the material in the gearbox has improved. This combination of wider toothfaces and better material has had a great effect on the increase of life of the gearbox. It has also tended to make it noiseless. The throw of the gearshifter lever in making changes, is less than it was. This is due to shorter shafts in the gearbox to secure the maximum stiffness and to avoid changes in alignment.

The location of the gearbox is an interesting study. Ever since 1910 the percentage of those using the amidship location has steadily decreased and the chart indicates that this decrease has been practically uniform. Starting with a record of 75 per cent. of all the installations in 1910, the drops during the succeeding years have been to 67, 55, 46, 39 until 1915 when it is 32.5. In almost inverse ratio the unit power



DISK AND CONE CLUTCHES
The fight for supremacy between the disk and cone clutch has resulted in a practical deadlock since 1910. As will be noted from the curve, cone clutches were over the 50 per cent. line but once, whereas disk clutches have passed it three times



IGNITION FLUCTUATIONS
Dual ignition was gaining ground until 1913, when the rapid introduction of electric starting caused the falling off of its progress and the growth of the single system

plant has been increasing; whereas, in 1910 it was only used in 10 per cent., it has steadily increased until in 1915 the figure is 49.3 per cent. In 1911 it was 16; in 1912, 25.

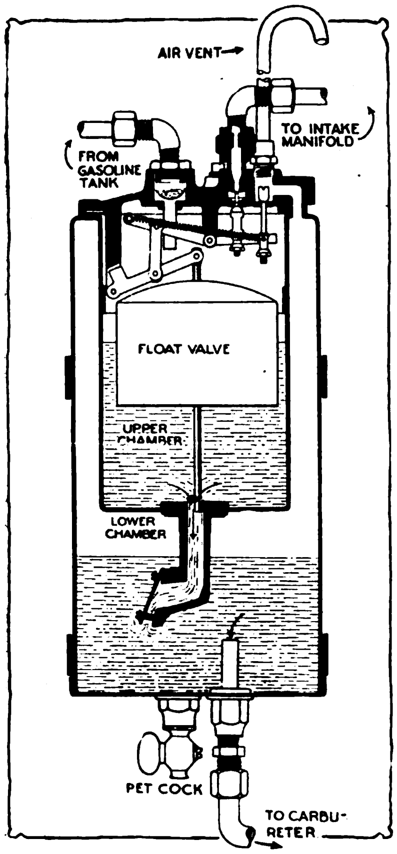
The percentage of cars using the gearbox in a unit with the axle has not varied much in the past 5 years. In 1910 it was 15 per cent. and in 1915 it is 18.2 per cent. In the interim it has been up as high as 20 per cent. which position it held for the years of 1912 and 1913, but in 1914 it was at its lowest since 1910, being 15 per cent. In other words it is again on its way towards a more popular position, having gained 3.2 per cent. during the past year. This is due in part to the discontinuance of a few concerns that used other gearboxes and also to its adoption by Chalmers, Mitchell, Saxon, Trumbull, Twombly and Vixen. On the other hand Maxwell, Studebaker and Velie have abandoned it.

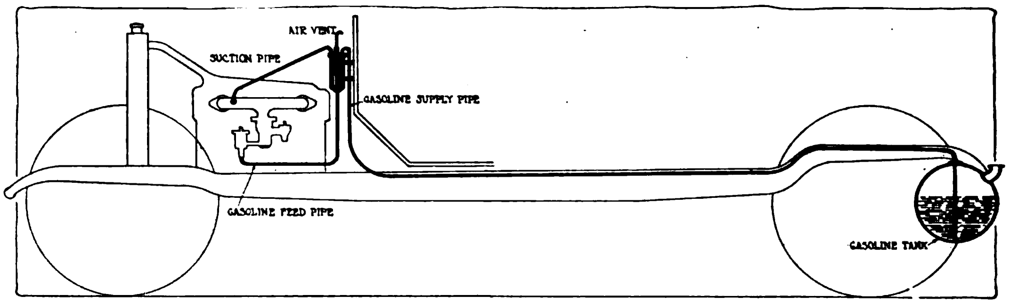
Unit Power Plant Gains

There is no doubt that the unit power plant and the block-cast motor which has gained substantially in popularity during the past year are complementary effects of the same trend. Three-point suspension is another effect of making the entire motor in one single unit in conjunction with the housing for the gearbox and clutch. This use of a flexible support which is independent of frame stresses finds favor on 90 per cent. of the block-cast motors.

Four-speed gearboxes reached their highest percentage in 1914. In this year 29.5 per cent. were so equipped. For 1915 the percentage has dropped to 23.5, a loss of 6 per cent. of the installations, giving a corresponding gain for the three-speed of 7 per cent. Those who have abandoned the four-speed gearbox during the year are Austin, Cameron, Interstate, Kline, Moon and Rayfield. In addition several who used it are now out of business, for example, American, Correja and Vaughan. Friction drive and two-speed gearboxes have lost ground. This is in line with a steady development of trend since 1910.

Floating axles, while not as popular as 2 years ago are still





VACUUM FUEL FEED SYSTEM

Vacuum feed is one of the infant prodigies of the past year, having grown from an unrecognized factor in 1914 to more than 20 per cent. for 1915. Its introduction has caused a marked rearrangement in tank locations

used on more chassis than all other types together. The curve of popularity has had a rise and fall. Starting in 1912 with 50 per cent., the figure for 1913 was 67 per cent., for 1914, 65 per cent. and for 1915, 56.5 per cent. The high spot was 1913. The reason for the falling off in popularity of the floating axle is in the introduction of a large number of low-price cars. The floating construction is more expensive to manufacture and the lower-priced cars as a rule use the other designs.

Semi-floating axles have decreased in popularity steadily since 1912, having traveled down the scale from 49 per cent. to 23 per cent. The percentages year by year were: 1912, 49; 1913, 26; 1914, 17 and 1915, 23.

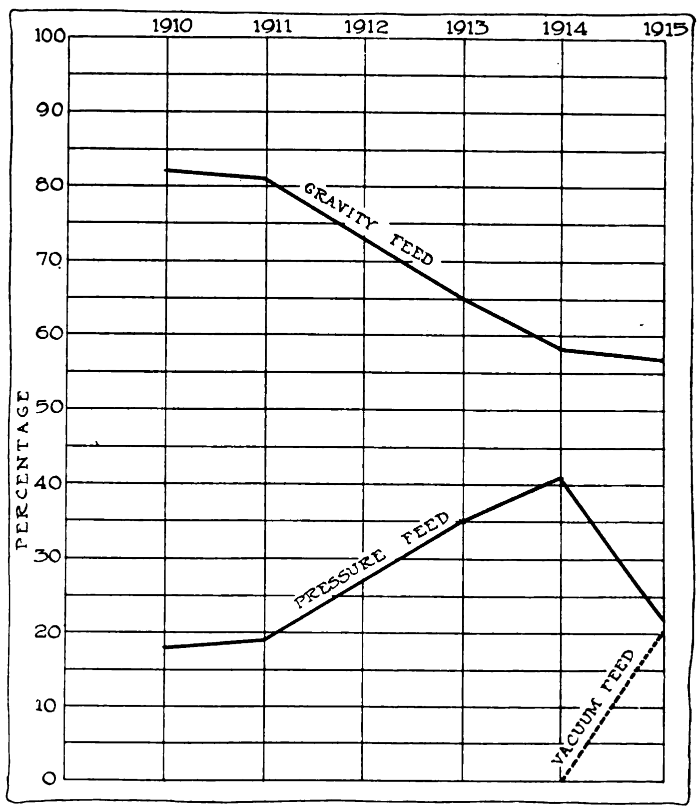
Three-Quarter Floating Axle Coming

The three-quarter floating axle has grown in favor from 4 per cent. in 1913, when it was introduced, to 18.5 per cent. in 1915. It has found favor on the medium-price cars because it offers the desired amount of bearing surface for the rear wheels, is accessible and at the same time is cheaper to manufacture than the floating design.

With alterations in axle design, a change has begun to make itself felt in the arrangement of the final drive. The spiral bevel rear axle has increased from 1 per cent. in 1914 to 9.5 per cent. in 1915. Worm drive has increased from 1 to 1.5 per cent. and chain drive from 4 to 4.5 per cent. These upward trends have cut into the numbers of those using the orthodox shaft and bevel with the result that in place of the 93 per cent. of makers who had cars so driven in 1914, only 84.5 per cent. have the bevel drive for 1915.

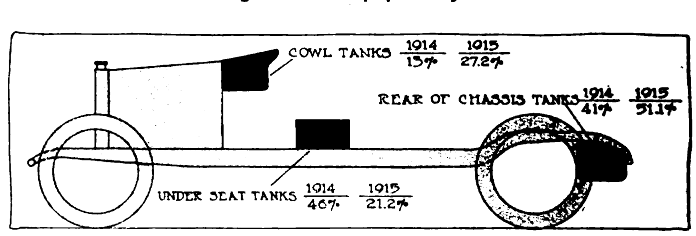
Spiral-Bevel a New Factor

Following Packards lead of a year ago the spiral-bevel drive has met with immediate favor. It has been now adopted by concerns such as Hudson, Cadillac, Reo, Speedwell, Marmon, Jeffery, Winton, Peerless, Stearns, Singer, Crawford, Cunningham, Dorris, Franklin and Kline. The difference in efficiency between the spiral-bevel and the straight bevel gear is so small that none of the makers who have adopted it think the power sacrificed to gain silence is sufficient to even reckon among the serious power losses in the car. Some state that the spiral-bevel is about 2 per cent. less efficient than the straight bevel under loads ranging from 8 to 45 horsepower. In addition to the silence, another advantage which is claimed for the spiral gear is that it does not require as careful handling in the matter of adjustments. In other words an adjustment which would be very bad in the straight bevel type would be perfectly quiet in the helical, due to the gradual engagement of the teeth as compared with the shock engagement with the straight bevel. On the whole, tests show that the helical bevel is just as efficient under all conditions as the straight bevel. The reason that the helical gear is an improvement is that in the straight tooth bevel gear any given tooth goes into or out of mesh at one time along its entire length. In the spiral-bevel the meshing starts



FUEL FEED SYSTEMS

Gravity feed has lost ground since 1910. Pressure gained since 1910 in the same proportion until the introduction of vacuum feed in 1914 caused a falling off in its popularity



TANK LOCATION ARRANGEMENTS

Vacuum feed is responsible for the changes in tank location. To show its effect the figures for 1914 and 1915 are given in the diagram above at one end of the given tooth and gradually moves toward the other end and the unmeshing does the same. There are at least two helical teeth in partial mesh all the time.

The problems of body room and clearance brought up by the overhead and under worm are not met with in the spiral-bevel, which takes up no more room than the straight bevel.

Outside of the axle construction of the rear system the materials employed have also, especially on the higher-priced cars, undergone a change for the better. The cars for 1915 are using more vanadium and chrome-nickel steel in the gears, not only in the gearset but in the differential, than any previous years. Nickel-steel shafts for the main drive and for the axles are also stronger than ever before, giving the car greater life. Broader bearing and tooth surfaces are also universal. Tubular drive shafts are now used on many cars; for example: Velie, Jeffery, Oakland, Hudson, Pierce, Peerless, Winton, Cunningham, Stearns, Dorris, Lexington, Moyer and Premier. Nearly all these are new.

Fifty-two Have Spring Drive

The method of taking the propulsion of the car and its suspension have changed together. Fifty-two manufacturers making ninety-five chassis drive through the spring. This is a percentage of 48. Following this in popularity in the manner of taking the drive is the torque tube which is used on 26 per cent. Radius rods take the drive in 26 per cent. and the torque arm in 6 per cent. Eighteen manufacturers, or 15

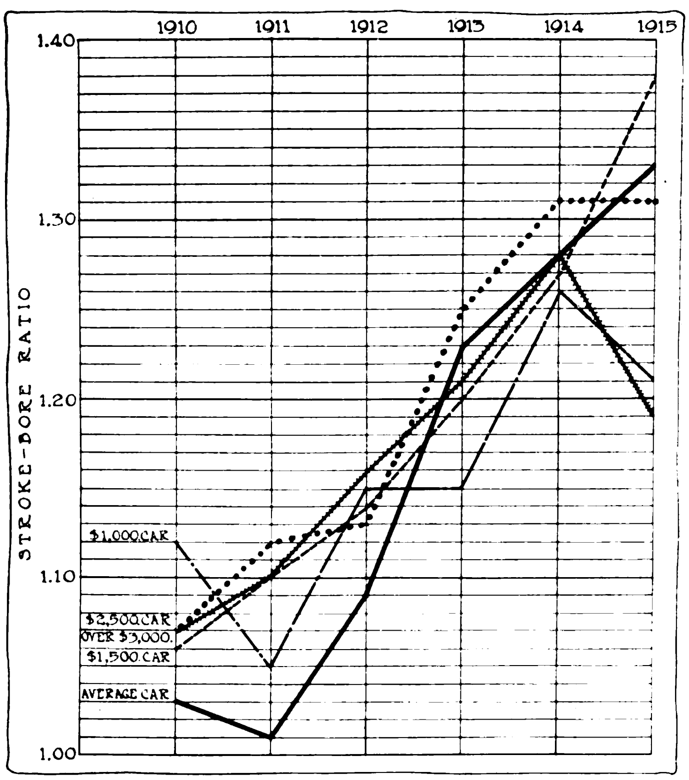
Block Castings the Big Trend

67.5 Per Cent. of Cars on Market Use Block Types—Sixes Increase by 2.5 Per Cent.—I-Heads Gained—Stroke-Bore Ratio Higher—Horsepower Lower

AN avalanche towards block-cast motors is the feature of motor development for this season. Of the 200 odd chassis on the market this season, 67.5 per cent. have their cylinders formed in a single casting as compared to 39 per cent. last season. The result of this change is exhibited all through the car. Without an increase in wheelbase makers have been able to provide more body space, owing to the shorter hood. The opportunity for inclosing every moving part of the motor afforded by the block casting has been taken advantage of to simplify the exterior. Coupled with the increase in unit power plants and three-point suspensions, the block-cast tendency has resulted in the adoption of a compact unit in which the clutch and gearbox housing are a part of the crankcase and in which all four or six cylinders are in one piece.

Some of the notable concerns who have adopted or returned to block casting in some models, during the year, are: Overland six, Chalmers six, Cole six-50, Enger six, Haynes, Norwalk, Peerless, Pullman, Stearns, Stutz and Velie. In addition to these there are a large number who have gone over to the block type of casting in one or two models, making their entire line block-cast. Apperson, Austin, Lenox and Moon are examples of this. Another reason for the growing percentage of blocks is that a large number of the new makers who have entered the field have used the block method of casting. Dodge and Scripps-Booth, who has abandoned the cyclecar, are two examples.



Above set of curves shows the general upward trend of stroke-bore ratios during the past 5 years. The average car has increased in stroke-bore ratio steadily since 1911, but those in the different price classes have risen and fallen during this period. The general upward trend, however, will be noted from the inclination of the average curve

Block Sixes Increase

It is in the six-cylinder motor that the increase of block castings is the most remarkable. A year ago some makers were inclined to be dubious of the six-cylinder block casting, believing that it was apt to be of inferior workmanship and consequently would result in an increased percentage of scrapped material. The improvement of foundry work has done much toward eliminating this fear, and consequently pair castings have fallen from 42 per cent. in 1914 to 27 per cent. in 1915 and casting in threes has also dropped from 13 per cent. to 10.5 per cent. In proportion six-cylinder blocks have risen from 45 to 63 per cent. during 1914.

In cylinder shapes the trends noticed in 1914 have been accelerated. In place of the gradual dropping off of T-head cylinders from 31 in 1913 to 30 per cent. in 1914; a quick fall to 16.5 per cent., has resulted from the marked gain of the L-head cylinder and also from the slight gain of the valve-in-head motor. For 1915, 70 per cent. of our motors have L-head cylinders, a fact not a little accounted for by the adoption of the block design. The L-head lends itself better to this method of casting than any other and these two developments have gone hand in hand until they now are the most distinguishing features of American design.

I-Heads Increase

The bulwarks of I-head construction continue to be such concerns as Buick, Franklin, Chevrolet, and Dorris, whose entire line is so constructed. Only two have dropped out. These are the Knox Automobile Co., and Cameron and they may not be out long. In addition to those who have had valve-in-head motors for the past few seasons there are new recruits who are instrumental in bringing the percentage up to its 2.5 per cent. gain. Among these may be mentioned Chalmers, Olds, Partin, Grant, Kearns, Owen and F. R. P. The total percentage of I-head motors is 8.5 as against 6 for 1914.

A 2 5 per cent. increase in valve-in-head construction gives rise to the question as to whether or not we are on the threshold of a marked change to this style of motor. The practice of overhead camshaft in connection with the valve-in-head motor has driven its entering wedge into the industry. The Weidely motor now sold for the trade and the new F.R.P. are two examples.

But all the developments in motors are not brought out in percentage tables. The growth of the long-stroke, high-speed powerplant is increasing. The stroke-bore ratio of American motors has risen in steady steps since 1911. At that time it was 1.01 to 1, now it is 1.33 to 1 on the average car.

Longest Stroke 7 Inches

Mitchell-Lewis and Pierce bear the distinction of having the motors with the longest stroke, this dimension being 7 inches. Fiat follows with 6.69 inches. There are several motors with 6-inch stroke among whom may be mentioned Peerless and Moline. Perhaps the most radical change in motor specifications is in the Inter-State which went from a six-cylinder 4 by 5 in 1914 to a four-cylinder 3.5 by 5 for

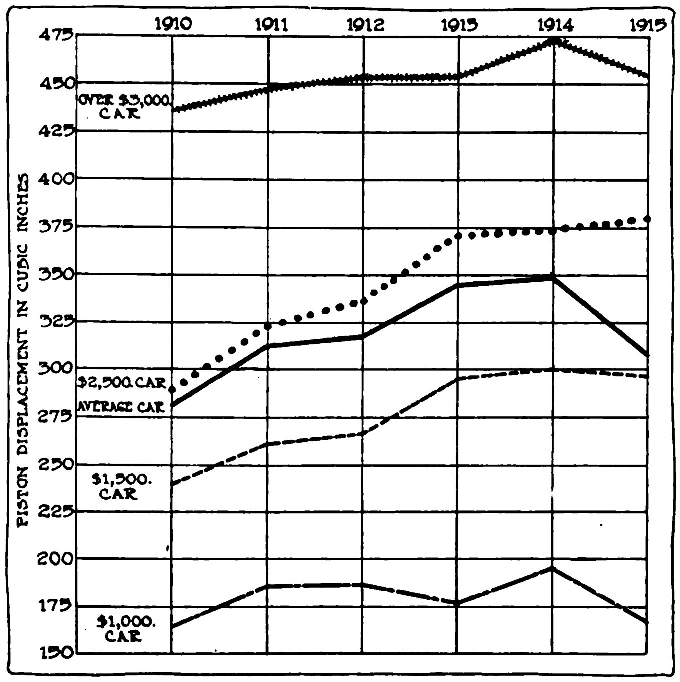
1915. The greatest stroke-bore ratio is that in the 4 by 6 cars which is 1.66.

In spite of the increase in stroke-bore ratios the square motor is not a thing of the past. One of our big-output manufacturers Buick, still continues to market a 3.75 by 3.75. There are no automobile companies listing motors with the stroke shorter than the bore. A big factor in the increased stroke-bore ratio is the gain in popularity of the 3.5 by 5 motor. This is used in 12 per cent. of our chassis, both fours and sixes. In 1914 it was only used in 4 per cent.

This lengthening of the stroke is not the only factor that has changed since the inception of the high-speed type. Lighter reciprocating weights have been such an object in motor design that it may be said conservatively that 5 per cent. has been cut from the weights of piston and connecting-rod assemblies.

The S. A. E. horsepower of the American motor for 1915, when taking the average of the entire gamut of cars, is 29.97. In 1914 it was 33.2, and yet were the formula neglected and the dynamometer test substituted as the judge of power, the 1915 motor with its smaller bore and greater stroke-bore ratio would doubtless outrank those of the past two seasons. It is certain that with its better balance and lighter parts that vibration would be found to be greatly reduced and the motor life correspondingly lengthened.

The figures for piston displacement reached their zenith in 1914. At that time the average American motor had a



Piston displacement has fallen off in every car except in the $2,500 range. Here it has gone slightly upward.

CYLINDER SHAPES PERCENTAGE	L-HEAD	T-HEAD	I-HEAD	KNIGHT
1910	56%	20%	18%	0
1911	60%	22%	14%	1%
1912	55%	30%	9%	2%
1913	56%	31%	9%	3%
1914	59%	30%	6%	3%
1915	70%	16.5%	8.5%	3%

The trend toward the L-head motor has been greatly accentuated for the 1915 season. The I-head is gaining slowly and the Knight holds its own

displacement of 349 cubic inches. This figure was reached after a steady rise from 1910 when the figure was 281.5. For 1915 it has dropped to 307.38, less than at any time since 1911. The efforts of designers toward securing better economy and more power from smaller motors are responsible in some degree for this reduction, but the addition of a large number of small cars which are of the class known as miniature automobiles has also been a deciding factor in reducing the displacement figures. In 1914 the cyclecar was a separate proposition and was not considered in averaging dimensions of the standard automobile. This season the cyclecar movement in greatly reduced form has been merged with the industry as a whole, taking the form of the miniature car.

The fact that the six continues to hold its own notwithstanding the large number of small fours, shows that the manufacturers struck a responsive chord in the purchaser when following the landslide toward the six-cylinder car which has grown steadily for 5 years. For 1915 47.5 per cent. of all our cars are sixes and 51 per cent. are fours. In 1914, 45 per cent. were sixes and 54 per cent. fours. The drop in fours has been in part accounted for by the practical elimination of the two-cylinder car and the introduction of the eight.

New entrants into the four-cylinder field are such concerns as Argo, Bauer, Briscoe, Dodge, F.R.P., Kearns, McIntyre, Remington and Sphinx. These with the exception of Dodge, Kearns, McIntyre and F.R.P. are in the small car class. In addition to these there are concerns who in 1914 made no fours but have re-entered the field for 1915. For example there are Inter-State and Peerless.

New Six Makers

To offset these additions and still have an increased percentage of sixes means that there must be several new names in the ranks of six-cylinder manufacturers. Examples of these are: Enger, Grant, Lexington, McIntyre, Monarch, Overland, Owen, Paige, Paterson, Pratt, Rayfield, Reo, Saxon and Singer. As a further aid to the cause of the six many former manufacturers of fours are now manufacturing other types. Examples of these are: Austin, Cadillac, Enger, Kline, Lexington, Monarch, Paige and Pathfinder. There are many others but these are typical examples. Such concerns as Enger and Paige have stopped making fours and are concentrating on sixes. Cadillac builds only eights.

A few have dropped out of the ranks of the six manufacturers. To give examples, there are Inter-State and Lyons.

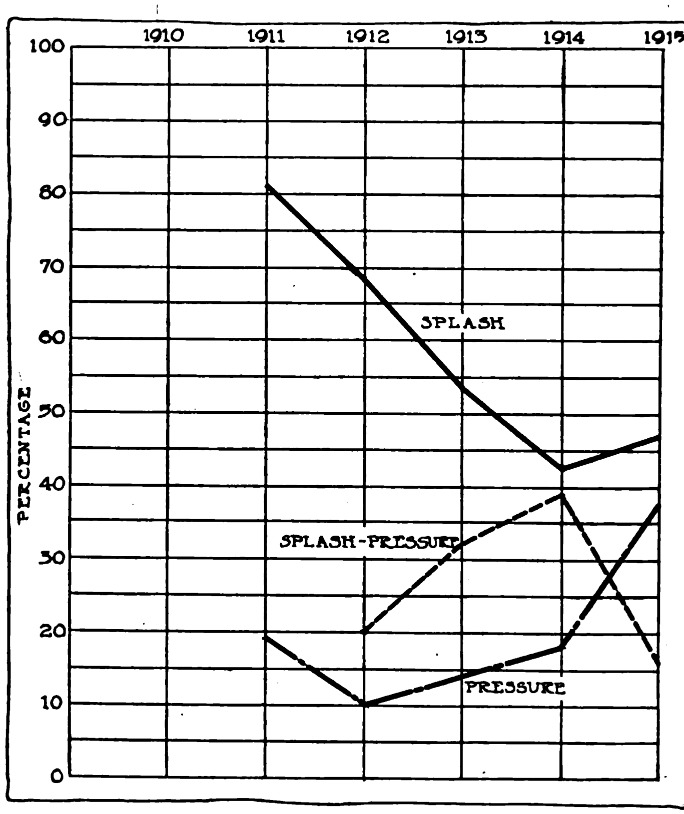
Several concerns that manufactured fours a year ago are not manufacturing at present, these including Cameron, Fal, Lozier, Marathon, Marion, Staver, Tribune and Ohio. There are also several names appearing a year ago as makers of sixes, and who have since ceased manufacturing, these including American, Colby, Correja, Henderson, Howard, Keeton, Knox, Lozier, Marion and Palmer-Singer.

No prediction of an eight-cylinder American car was heard a year ago yet at this time at least three manufacturers, Cadillac, King and Briggs, have cast their lot among those who believe in the double-four. With the necessity of arranging the cylinders differently in this class of motor the adoption of the larger number of cylinders has also marked the introduction of the V-type engine into the higher-priced cars. This, in turn, is the direct cause of other engineering developments which mark pioneer work for America. These are the yoke connecting-rod, and the other special designs necessary in arranging for the two blocks of four cylinders.

While helical gear drives for the camshaft still retain their supremacy the percentage of cars so fitted has dropped from 82 for 1914 to 76 for 1915. Spur gear drive on the other hand has risen from 10 per cent. in 1914 to 14 per cent. in 1915. Silent chain drive has risen from 8 to 10 per cent. The falling off in the helical gear percentage can be traced directly to the miniature cars. Concerns such as Argo, Cycleplane, Kearns, Peter Pan and Remington, who have brought out the new low-priced fours, do not use the helical gear, which is much more costly than the spur. Silent chain drive is used on the new Cadillac and King eights for accessory drives.

Stiffer Crankshafts Used

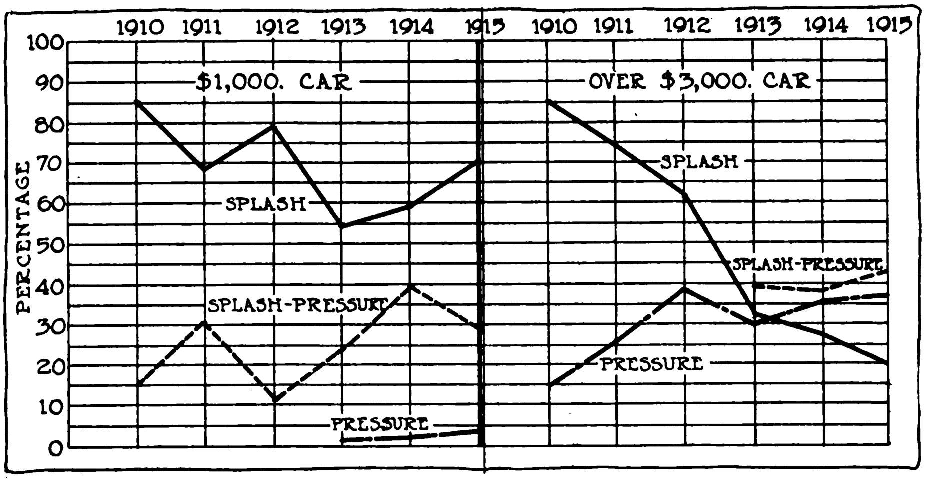
The shorter overall length of the block motor has resulted in a stiffer crankshaft but the higher speeds of the engine have increased the demands on the crankshaft to such an extent that manufacturers are still compelled to work towards an increased stiffness and strength. Larger diameters mean higher peripheral bearing speeds. The bearing is the shortest-lived part of the motor and to cut down its life still further is not desirable. To overcome this quandary manufacturers have been compelled to use the alloy-steel crankshaft and vanadium and chrome-nickel steel in this important part of the motor is not now uncommon. With the use of the alloy and a careful manipulation of the heat-treatment stiffness has not been sacrificed, while tensile strengths have gone up. It is not uncommon now to see crankshafts of 150,000 pounds per square inch tensile strength and yet with such



Both pressure and splash oiling systems are on the increase, but splash-pressure oiling is decreasing. The reason for the increase in pressure oiling lies in the use of the high-speed motor an amount of stiffness that the critical speed of vibration is above the demands of ordinary use. General practice in the average motor still favors the .40 carbon open-hearth steel for crankshaft work.

Connecting-rod practice has not changed materially. The use of alloy-steel has been common for the last 2 years, both chrome-vanadium and chrome-nickel playing an important part in the specifications. Many of the makers of lower-priced cars have found satisfactory results with .30-.40 carbon, acid, open-hearth steel, and as regards carbon content the choice seems to favor .25 per cent.

The use of tubular connecting-rods has been predicted by foreign engineers, but as yet no serious inroads on the ranks of the I-beam section have been made. The H-section connecting-rod holds its own in a small percentage of makes.

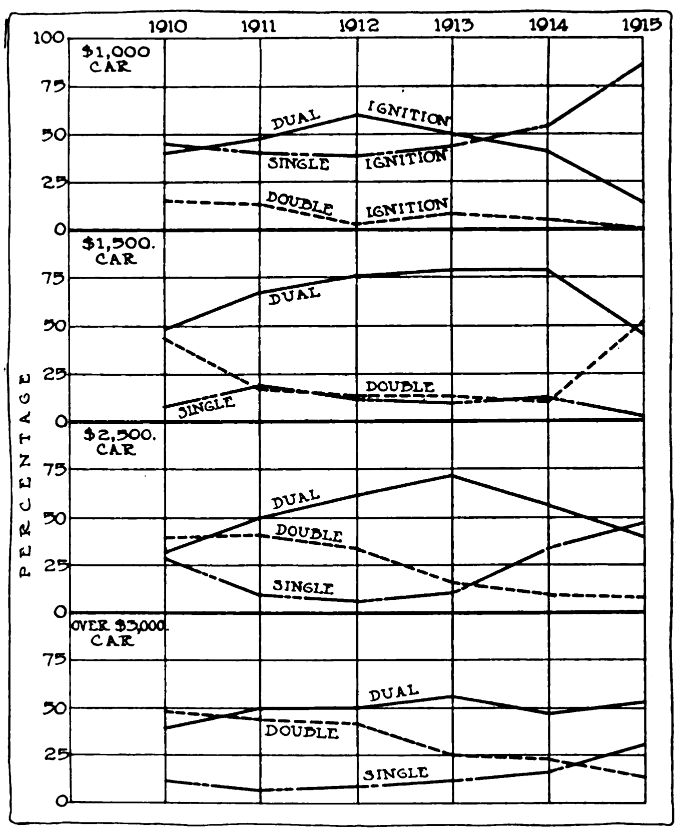


In every price class but that of cars selling for more than $3,000 dual ignition is falling off. In that class there is a slight increase. Single ignition is rapidly increasing all along the line, the reason for this being the introduction of the electric cranking outfit

It is but natural that in the search for lighter parts a few tubular constructions should begin to make their appearance. Three of the Knight cars are equipped with tubular connecting-rods. These are Moline, Stearns and Lyons-Knight. In addition to these examples there is the new F. R. P.

Lightweight Pistons

Pistons are longer and lighter, which means thinner than in 1914. Weight has been saved in the thinning of the webbing. Neater core work, especially as regards the space surrounding the piston-pin boss has made a lighter job but perhaps the biggest saving in material and weight is in the piston rings. The practice of using fewer rings at the top is growing rapidly. With the decrease in the number of rings, it is but natural that efforts would be made to make the rings themselves more efficient. The result is the growth of improved types of rings. The laminated or multiple design in which the ring is made up of several layers of metal is one instance of this. Another tendency in piston ring practice is to buy the product of specialists in piston-ring manufacture. These, as much as carbureters and magnetos, are designed with the special purpose in view of being the most efficient units for the functions that they must perform. The makers of these specialized products have secured patents on improvements of which the motor makers are beginning to be glad to avail themselves. They are proof against leakage and serve the same purpose as two or more of the ordinary rings without noticeably increasing the friction.



Splash and splash-pressure oiling are taking opposite trends in the $1,000 car. Pressure oiling, which was introduced in this class in 1913, is slowly making itself felt. In the higher-priced car the splash-pressure system is supreme, but the pressure feed is rapidly gaining

The rings used may be generally divided into two classes, the compound ring in which there are two or more complete separate rings of metal, and single rings. In the compound rings the increased surface and the staggered joints eliminate leaks and increase the life of the ring. In the single rings various lapping joints are used to insure continuity of the bearing surface and at the same time to prevent leakage.

Bearing Length Increased

Higher speeds mean reduced bearing life. When the designers increase the revolutions per minute of their motors it means an increase in bearing surface to make the life of the bearing remain the same. Increase in bearing surface has been gained by increasing the length of the bearings, although it is doubtful if diameters, on the whole, show any marked increase. Nineteen hundred and fourteen was the year of bigger crankshafts and when these reached their limit it was necessary to go into greater lengths. With the mounting of the cranking motor on the flywheel an increase of bearing length to take the side thrust of the cranking motor was required on the rear bearing. The result is an almost universal tendency towards longer rear main bearings.

In the exterior fittings of the motor greater accessibility exists throughout. The adoption of vacuum-gravity gasoline feed has enabled the carbureter to be mounted much higher than on gravity-fed cars. The raising of the carbureter is synonymous with the shortening of the intake manifold header, and in many instances the latter is eliminated altogether and the carbureter is bolted directly against the casting which contains the intake manifold as an integral part. When the carbureter bolts against the casting a vertical flange is most often used. This has led to the development of the horizontal type of carbureter. Overland, on the new six uses a short elbow to retain the vertical carbureter and on cars using the new high-speed Continental motor the carbureter is bolted directly to the cylinder block on which there is a vertical, integral flange.

The raising of the carbureter has cleared the way for accessibly mounting the horizontal shaft driving the water pump, magneto, generator and other auxiliaries. It is a growing practice to extend the web at the juncture of the two halves of the crankcase making this horizontal flange a shelf to carry the entire auxiliary layout. This is one of the steps towards the clean exterior maintained on this year's motors.

Thermo-Syphon Cooling Gains

Thermo-syphon cooling continues to increase in percentage. For 1914 its chief advocates were among the lower-priced cars. It is now used on 27 per cent. of American chassis as compared to 19 per cent. Pump circulation is used on 72.5 per cent. This is a falling off of 6.5 per cent. as compared with 1914 and the reason can be assigned to the introduction of the miniature cars.

Air cooling has dropped from 2 per cent. to .5 per cent., now leaving Franklin as the only exponent of this method of cooling. In connection with this it is only fair to mention the successful demonstration made in the fall of this year by the Franklin motors, which, driven by representatives all over the country, successfully negotiated 100 miles on low gear without overheating.

Another big influence in the falling off of the air-cooled motor is the practical elimination of the cyclecar as a factor in the industry. Many of these cars had motorcycle motors with air cooling ribs. These have now disappeared and in their place are the small thermo-syphon cooled fours. The Duryea is an example of air-cooled car listed for 1914 but not included in the 1915 lists.

The arrangement of the valves has been greatly improved. The redistribution of the auxiliaries due to the higher mounting of carbureters, which in turn is a development due to the introduction of vacuum feed to a large extent, has allowed for the more accessible placing of valve adjustments. There can be no doubt that the intention to make exteriors simple and accessible has been a leading factor in development, and full advantage has been taken of the higher carbureter to place the valve adjustment parts in reach. Another valve development continued from 1914 and augmented this season is in the adoption of the tungsten steel valve. A score of representative makers are using these valves to eliminate the necessity for grinding. Many use them for the exhausts only and for the inlet employ nickel steel.

Bigger Waterjackets

Another point in which an improvement has been made in water circulation is in the employment of larger waterjackets by practically every manufacturer who has redesigned his motor for this season. The tendency, is to have a greater volume of water surrounding the cylinders and also to have this greater volume in constant circulation. We find, therefore, that water pumps are also more efficient or larger; and radiators of increased capacity. Hupmobile and Winton are good examples of those who have increased their radiator capacity.

There are three primary classes of motor lubrication. These are the splash, pressure, and a combination of the two which can be called splash-pressure.

In the splash system every bearing is lubricated by the splash from troughs or wells beneath the connecting-rods. The oil may be fed by pump, which is the generally-used method, or by gravity from a tank. The oil may be recirculated or simply fed as required to replace that used. It remains a splash system so long as every bearing surface of the motor, cylinders, pistons, crankshaft, camshaft, wristpins and timing gears are so lubricated.

In the pressure system, the oil is taken up from a reservoir by a pump and forced under pressure to the main bearings. At these points it enters the hollow crankshaft and flows through this to the lower connecting-rod bearings. After oiling these it is forced through hollow leads to the wristpins and thence to the cylinder walls. There is no dipping of the connecting-rods into pools of oil but a certain amount of spray is always present. This is due to the oil thrown off by centrifugal force from the cranks. In a pressure-feed system the camshafts and the timing gears are generally oiled by independent leads.

Splash System Described

In the splash-pressure system the oil is carried under pressure to the main crankshaft bearings. The quantity pumped to these bearings under pressure is far in excess of that required to lubricate them. Consequently there is a continuous overflow which is utilized to fill the splash troughs or wells. The splash part of the system takes care of every bearing except the main bearings. There are many modifications of the splash-pressure system, some in which the camshaft bearings are fed by pump pressure direct, and others in which the oil under pressure is fed to the cylinder walls.

Motor lubrication, which was distinctive in 1914 on account of the increase in the number of those using pressure oiling, is like other features of the motor in enjoying an accentuated continued trend. Today 37.5 per cent. of our makes of cars are lubricated by pressure in which the oil is carried to the crankshaft bearings and thence by means of the hollow crankshaft to the lower connecting-rod bearings and finally through leads to the wristpins. The gain in pressure oiling is represented by the loss in splash-pressure systems. Splash oiling in which every bearing surface is taken care of by the lubricant splashed from troughs by the connecting-rods is also on the increase, having risen during the past season from 42 per cent. to 46.5 per cent. This is the first season in which no stock models are listed as feeding the lubricant with the fuel, since 1910. In 1913 and 1914, 1 per cent. of the manufacturers used this method and in 1910, 6 per cent. of our motors were so oiled. The elimination of the two-cycle motor is the reason.

Single Ignition Increases

The most striking trend in ignition is the adoption of the single system. There can be no doubt that if the magneto had not established itself as such an instrument of reliability, an even greater trend toward the single battery system would have been noted. As it is, single systems, whether by battery or magneto, have gained the ascendency, having displaced the dual system from the leadership. The reason for the adoption of the single system is in the success of the electric starter. Most manufacturers feel that it is no longer necessary to have one source of current for starting and another for running.

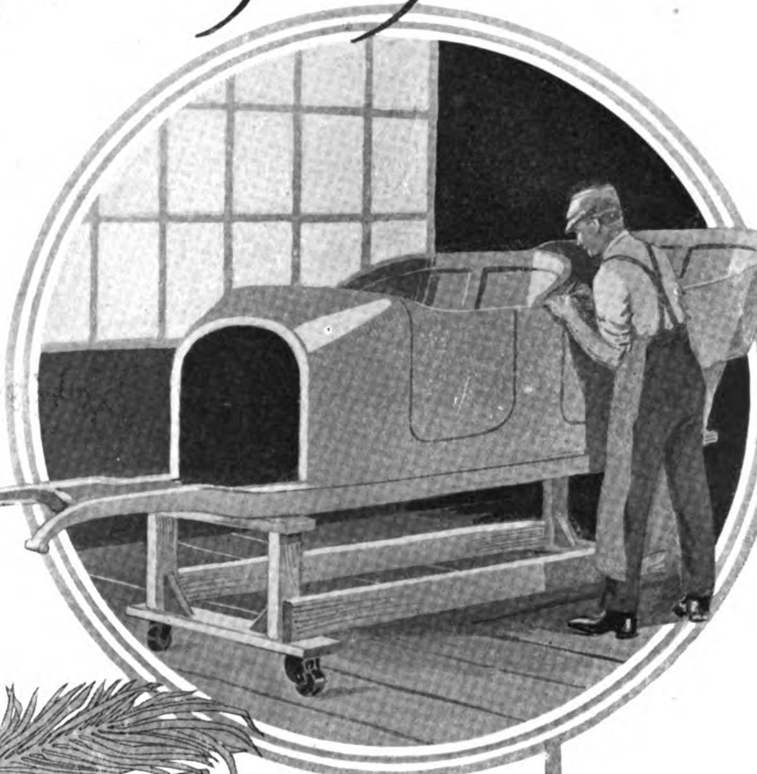
Where the single magneto system is used, it is considered that the cranking motor can turn the engine over so rapidly that starting on the magneto is as readily accomplished as starting on the battery. Where the single battery system has been adopted, it is because there is no need for two current generating outfits. The generator supplies the current to the battery and the battery to the remainder of the electrical instruments including the ignition distributer as well as the lamps and the cranking motor.

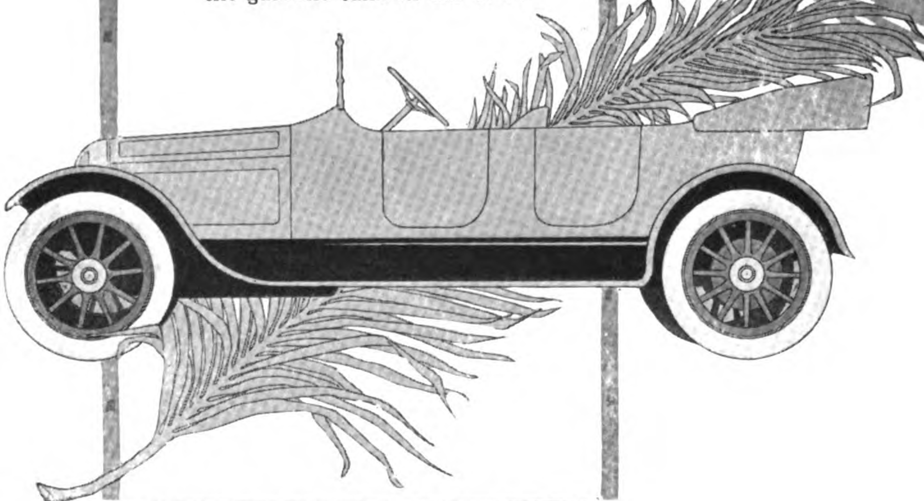
Single Ignition Gains

In the percentage column we find single ignition on 56 per cent. In 1914 it was used on but 23 per cent. While dual ignition was in the majority in 1914, having 50 per cent. of all the installations, it is now relegated to second place with but 36 per cent. Double ignition also continues to fall off. Last season 11 per cent. were so equipped. This year but 4.5 per cent. use it. Two-spark ignition is used on 1.4 per cent. this season as compared to 4 per cent. last, and duplex 2 per cent. for 1915 against 3 per cent. for 1914. The differences are absorbed in the gain in single ignition.

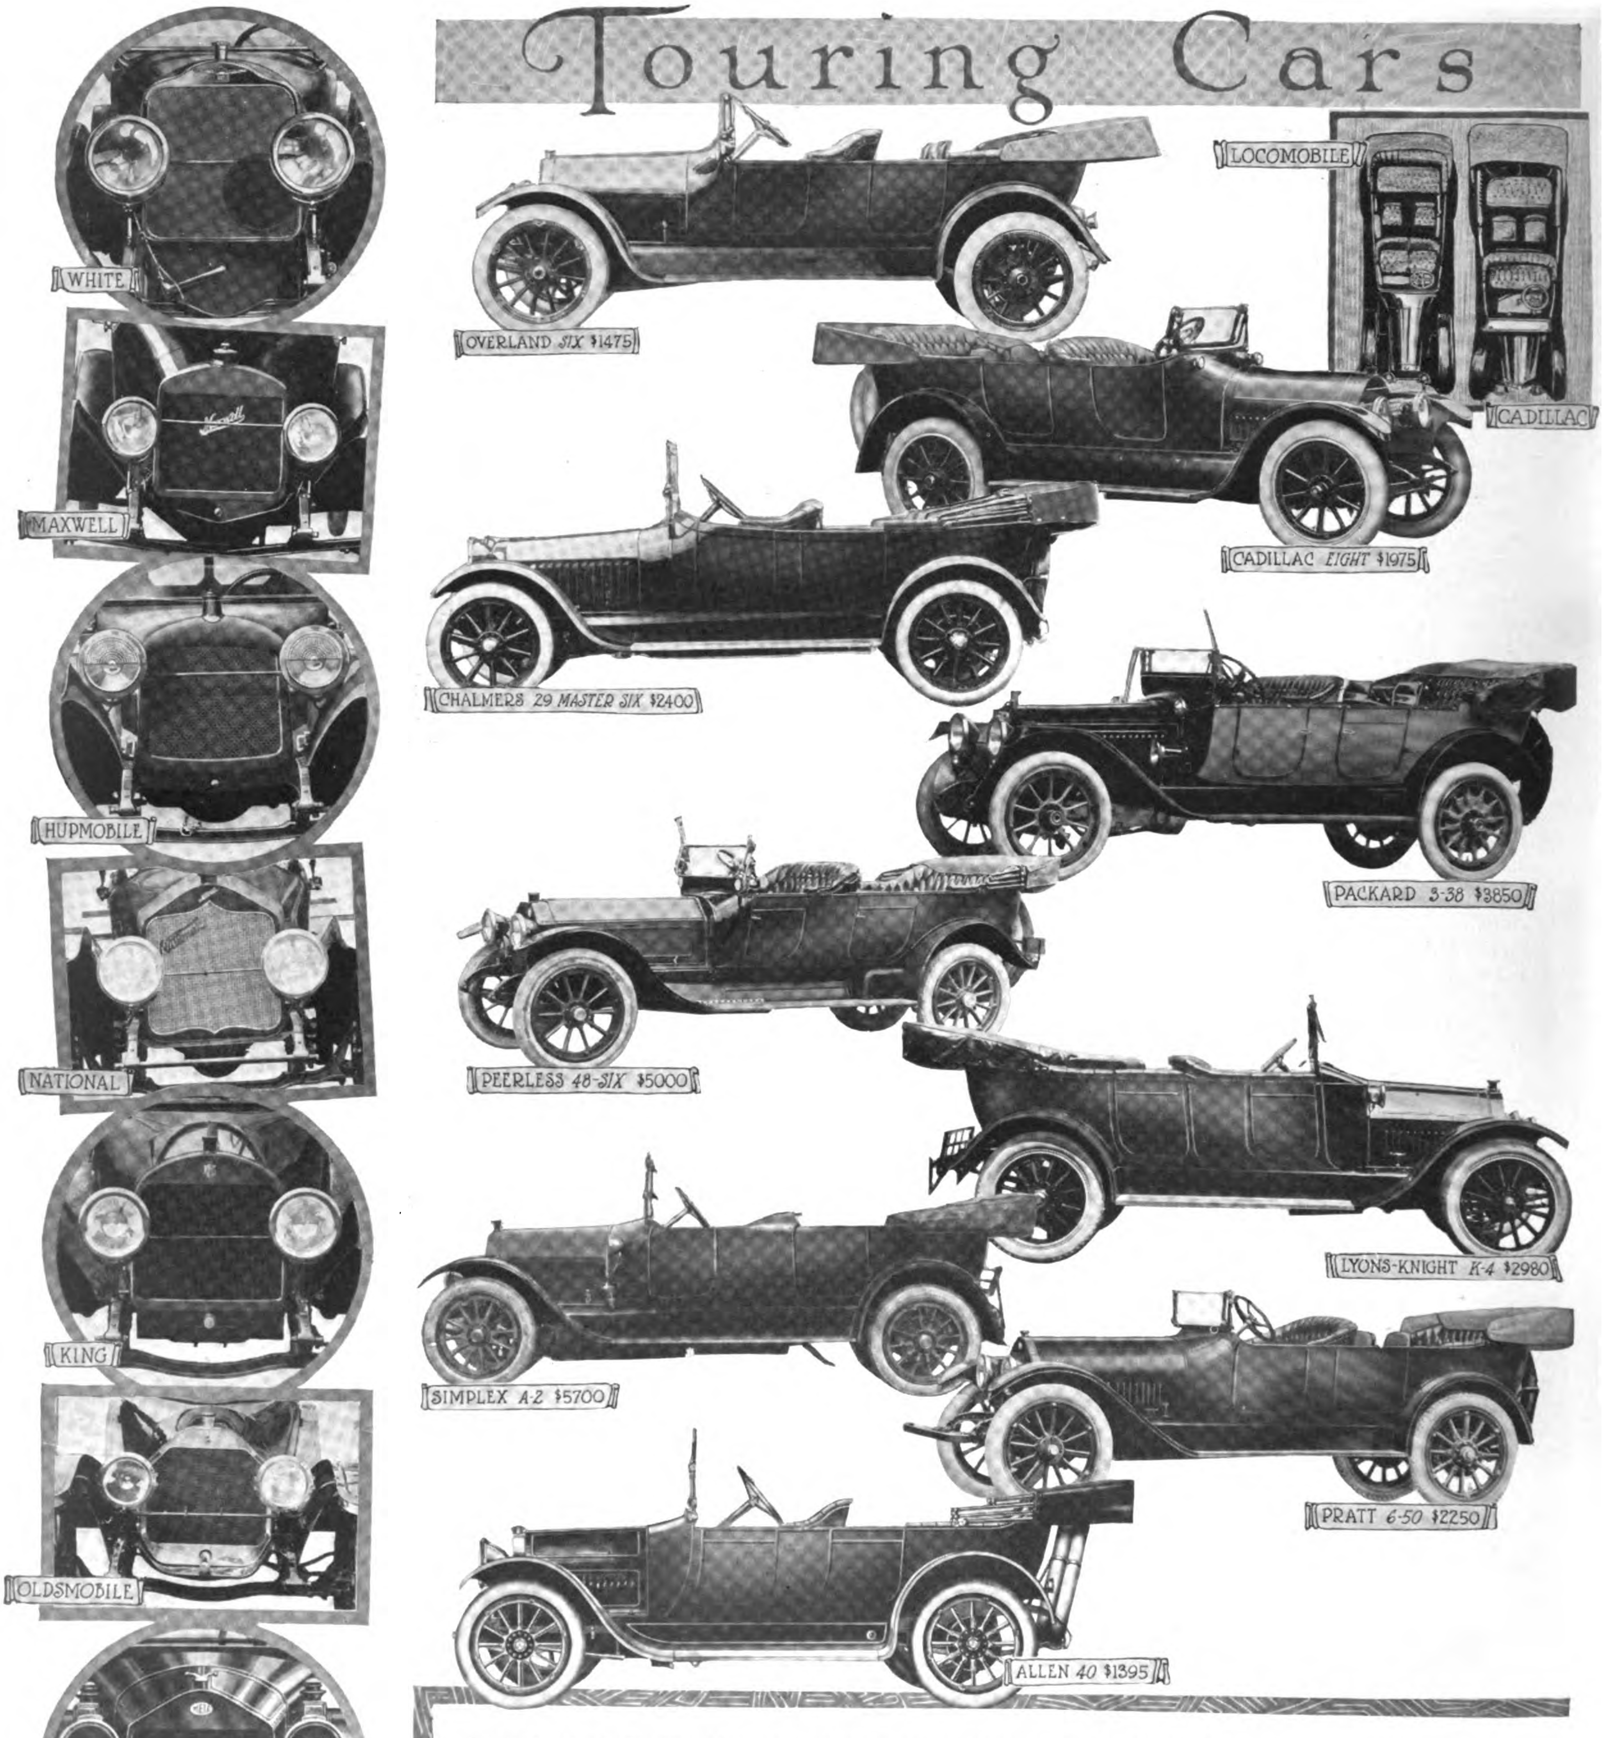
Car Bodies of 1915

FOLLOWING its custom of previous years The Automobile presents in the following pages its Car Illustrated Department showing the leading makes of open touring cars, runabouts and combination types for 1915. Grouping the makes side by side permits the reader to study the individual types and also to compare designs as well as enabling him to generalize on leading trends. An analysis of the groups shows a perceptible lowering of many designs and a greater effort to link the hood and body lines into one by a cowl that plays the part of a uniting member, not a few incorporating the gasoline tank in the cowl.





Touring Cars



Overland, 82, $1,475, Six, 3½ x 5¼, 125 W.B., 35 x 4½-inch tires.

Chalmers Master, Six, $2,400, Six, 3½ x 5½, 125½ W.B., 34 x 4½-inch tires.

Peerless, 48-Six, 4½ x 6, 137 W.B., 37 x 5-inch tires.

Simplex, A-2-38 H.P., $5,700, Four, 4⅞ x 6½, 137 W.B., 35 x 5-inch tires.

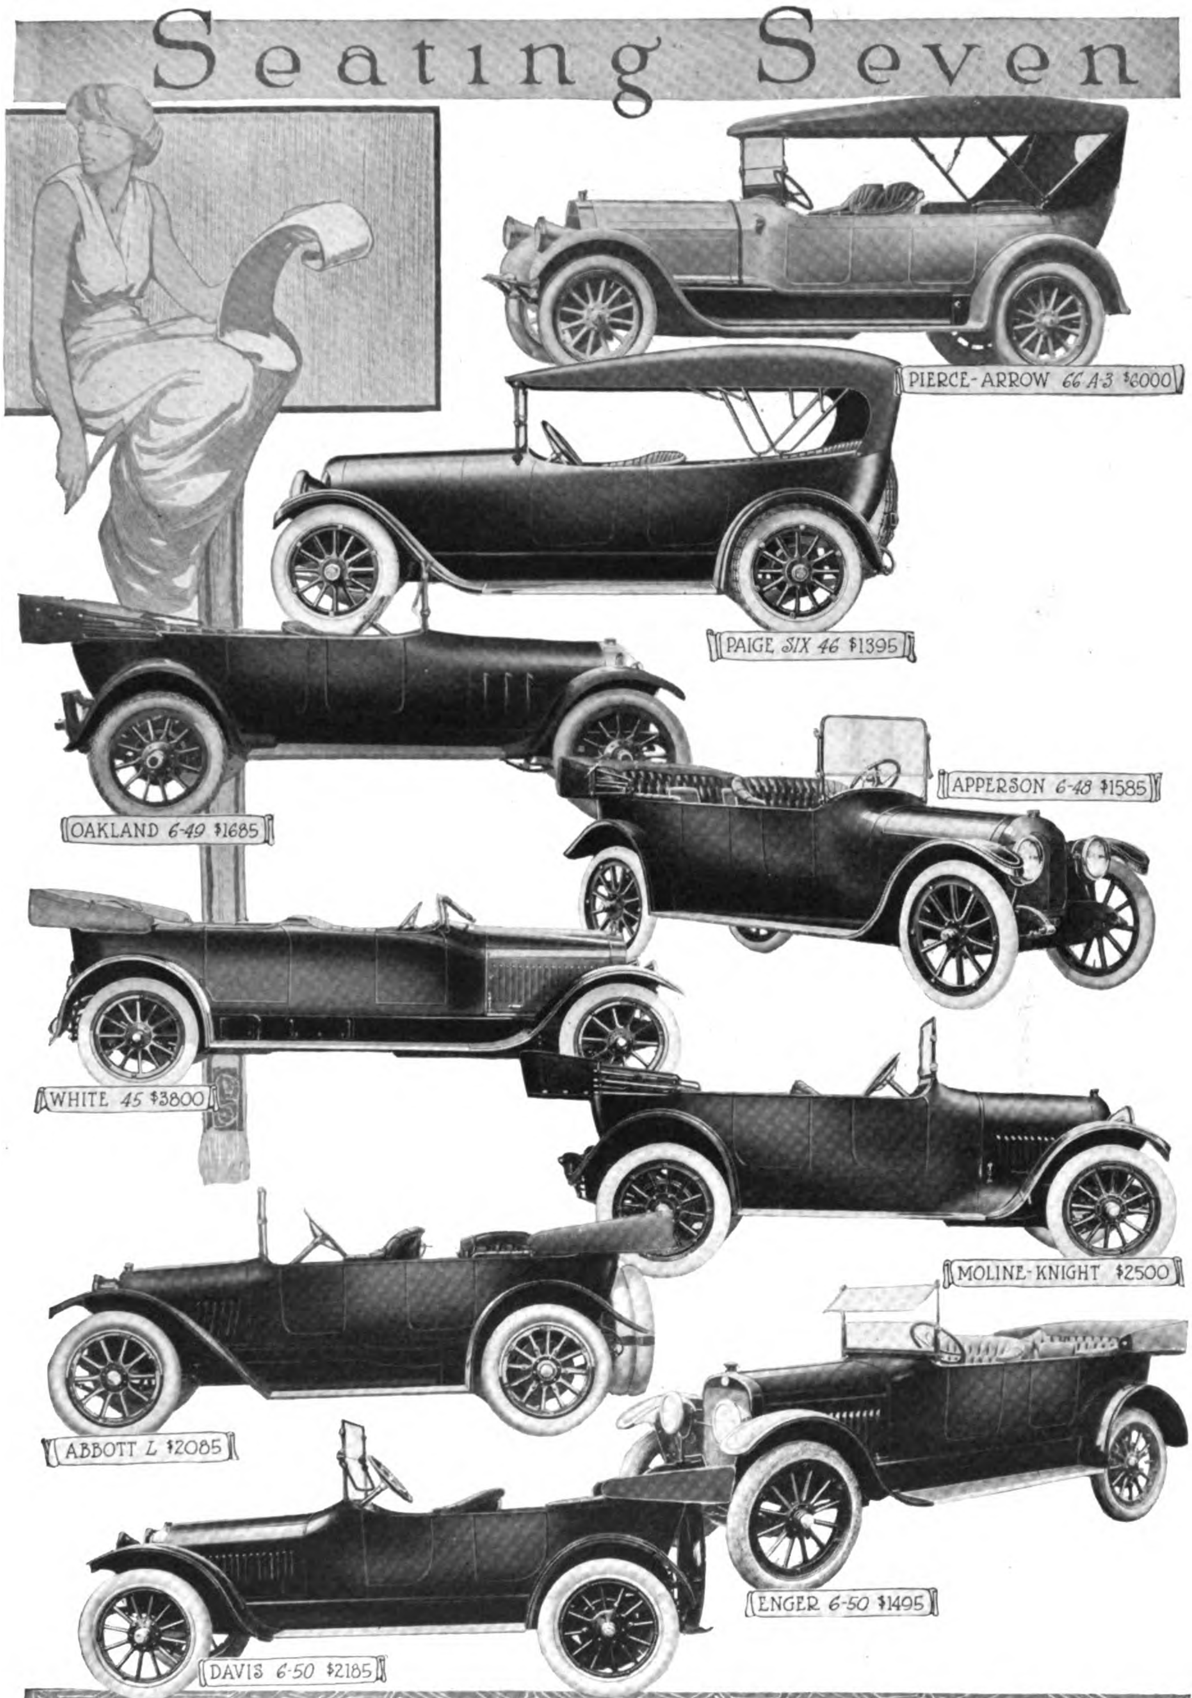
Allen, 40, $1,395, Four, 4⅛ x 5, 118 W.B., 35 x 4½-inch tires.

Cadillac, Eight, $1,975, Eight, 3⅛ x 5⅛, 122 W.B., 36 x 4½-inch tires.

Packard, 3-38, $3,850, Six, 4 x 5½, 140 W.B., 37 x 5-inch tires.

Lyons-Knight, K-4, $2,980, Four, 4½ x 5½, 130 W.B., 37 x 5-inch tires.

Pratt, 6-50, $2,250, Six, 3¾ x 5¼, 132 W.B., 37 x 4½-inch tires.



Oakland, 6-49, $1,685, Six, 3½ x 5, 123½ W.B., 35 x 4½-inch tires.

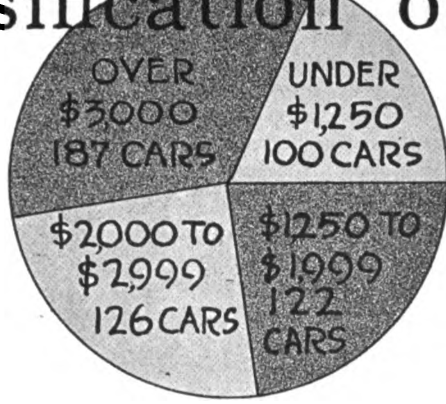
Price Classification of 1915 Cars



IN the following tables is given a list of American cars listed under four price classifications. These classes are divided as follows: The first includes all cars listing up to $1,250, the second all those from $1,250 to $1,999, the third from $2,000 to $2,999 and the fourth above $3,000.

These tables are a guide to the buyer. They tell him the type of body he can get on a car of any price. They give the power of the motor, the length of wheelbase, the tire size and left or right drive. The average price of cars in these four classes are as follows: $855, $1,419, $2,454, and $4,563. This is a reduction all along the line as compared with 1914 when the four prices of average cars were respectively $950, $1,650, $2,460 and $4,700. The average price for 1915 of all American cars is $2,005, for 1914 it was $2,635.

Automobiles Listing from $1,250 to $1,999

IN this price class which includes more chassis than any other, are the popular **$1,500** *cars. It is here that the low-priced six has come into its own. While last year only* **19** *per cent. of the chassis in this price class had six-cylinder motors, this year the percentage has jumped to* **55**. *The number of four-cylinder cars has dropped during the last year from* **81** *per cent. to* **40.2**. *Two makers of eight-cylinder cars have entered this field bringing the percentage of chassis so equipped up to* **4.1**. *There are now nearly as many eight-cylinder cars available in this price classification as there were six-cylinder cars in* **1912**.

*Rear tires only; front a size smaller. **2-door design.

Automobiles Listing from $2,000 to $2,999

WHILE there are only 75 per cent. as many makes in the $2,500 class the purchaser still has a wide range to choose from. There are forty-two makers listing fifty-four chassis upon which there are 126 different types of bodies. There are fewer changes to be noted in this class of cars than in any other, the size of the motor, the wheelbase and all the principal dimensions and practices of chassis work are the same. The price has varied so little that it can practically be said to be unchanged. Body refinements and better equipment, however, make the $2,500 car of this year a better value than that of last. It is in this class that many have gone from the five- to the seven-passenger touring car without altering the price.

Tables a Guide to Purchaser

ALTOGETHER this season, there are 119 makers listed in the annual tables. Many of these are selling cars that fall into different price classifications, but a small majority are found in the two lower-priced classes. In cars selling up to $2,000, there are 100 makers, fifty making cars selling below $1,250 and fifty from $1,250 to $1,999. There are forty-two manufacturers of cars selling between $2,000 and $2,999 and thirty-four selling above $3,000.

Out of 535 American cars, 187 are priced at more than $3,000; 126 between $2,000 and $2,999; 122 between $1,250 and $1,999 and 100 at less than $1,250. Thus we find that the makers of the high-priced cars offer their purchasers a larger choice of bodies than do the low-priced and intermediate manufacturers. Out of the chassis offered this season there are forty-eight carrying bodies priced above $3,000, fifty-four carrying cars between $2,000 and $2,999; sixty-three between $1,250 and $1,999 and fifty-seven below $1,250.

Closed Body Developments

The tendency of the makers of higher-priced cars to offer more bodies, than those of lower-priced vehicles is due to the use of the inclosed body on the higher-priced car. Those who go into the inclosed coachwork at all generally find it more profitable to manufacture three or four types of inclosed bodies rather than to bend their efforts solely towards one. While the limousine, in the first few years of inclosed body design, was supreme, its claim for first place is being challenged by the sedan and landaulet.

In the tables given on these pages the purchaser is fully informed regarding the style of body and seating capacity which the various makers are producing. The price is also given together with some of the leading specifications.

About one-quarter of the manufacturers of cars listing above $3,000 have dropped from the ranks. We miss this year such familiar names as those of Lozier, Knox, and others. But few have come to take the place of those who have dropped out. The new maker in this day of the light low-priced four and six hardly ventures to tempt fate by entering the lists with a high-priced car. On the other hand there is a steady demand for stable cars which have gained a reputation for themselves and which sell around the $4,000 mark.

While there are but thirty-four makers whose cars are listed above $3,000 more than 187 stock jobs are manufactured. The large number of cars in proportion to manufacturers is due to the practice on the part of several large makers to list a large number of inclosed bodies. As a matter of fact the list does not show the entire gamut of the high priced cars open to the purchaser. The Pierce-Arrow company, for example, lists fifty-four body styles as stock. This does not mean that these bodies are on chassis awaiting shipment on order, but it means that the patterns, drawings, etc., have been completed and are in the company's shop ready for use on order.

What is true of the Pierce company can doubtless be said of Packard, Peerless and other makers of high-priced chassis. These concerns have made but few mechanical changes during the year. Refinements in appearance which cannot be brought out by figures are universal throughout and withal there has been a price reduction of $140 on the average. The average car in this classification for 1915 sells for $4,563 whereas in 1914 it sold for $4,700. An increase of 1 inch in the average wheelbase has also been made and while it is not such a great percentage of length increase as to be of premier importance it shows that the trend inaugurated in 1911 and followed consistently ever since has not as yet passed this climax. The figure for average wheelbase is now 133.2 inches. The rise started in 1911 when it was 124 inches, jumping 5 inches in 1912, 1 inch in 1913, 2 in 1914 and now an additional inch for this season.

Many Roadsters and Touring Cars

While the greater percentage of bodies selling in the $4,000 class are the inclosed limousines, landaulets and coupés, a large percentage of the total are roadsters and touring cars. The Simplex company and the new F. R. P. are offering their cars in this class in chassis form, special bodies being put on to order.

Of the concerns selling cars in this price class only eight are listing but one chassis. The remaining twenty-six list from two to three. There are none who list more than this number. The concerns which only list one chassis are Austin, Cunningham, Porter, Morse, Owen, Republic, S. G. V. and Winton. Those who list three chassis are Peerless, Pierce-Arrow and White. There is only one concern making the high-priced car which lists only a touring body—this is the Republic. Nevertheless touring bodies are not slighted. Five manufacturers are listing those of four-passenger capacity, twelve of five-passenger capacity, five of six-passenger and eighteen of seven-passenger capacity. The most popular class of body among the $4,000 cars is the limousine. The landaulets and sedans run a close race for second choice in closed bodies being respectively 12 and 11 in number. In addition, six makers are offering coupés and six berlines.

Passenger Cars for 1915 Listed

ANNUALLY THE AUTOMOBILE publishes its table of specifications of American cars to serve as a reference during the year. The information given on these tables is taken from data sheets filled out by the respective manufacturers. This is gathered together up to the last possible moment and finally tabulated in the form below. Many of the manufacturers wait until this season of the year to make their first announcement of new models at the January show in New York. Their designs are kept secret and not shown until the exhibition.

Many of these models are described in this table but others do not appear and in a number of instances descriptions are given of the new cars in the review of the industry given on pages 1228 to 1260 of this issue.

In connection with the tables under price classifications, page 1215, the information in these pages offers a complete guide to the purchaser or student of the development of the automobile industry. In this tabulation, the cards of the manufacturer are laid upon the table and the practices which he believes are submitted to the scrutiny of those who are interested in the purchase or development of an automobile.

How to use the tables depends on the purpose of the user. For the purchaser the recommended method is to first turn to the pages of the buyers' guide, page 1215. Here will be found the names of the cars selling at the price it is intended to pay. The body styles and the principal questions of power and equipment will be answered. After the cars that meet the requirements of the buyer are selected from the buyers' guide, the table of specifications herewith answer the questions that the motorwise buyer will ask before making up his mind what car he desires.

The table follows a logical order through the chassis. First the number of cylinders is given and this season the choice of a four, six or eight will be found listed. The power of the motor is the next consideration and this is given completely by not only furnishing the bore and stroke but by giving the S. A. E. formula rating. As this formula is apt to hit under rather than over the power developed by the modern motor, the piston displacement is given in addition to complete the information.

Complete Story of the Motor

As well as a table can accomplish it the complete story of the motor is told by the details furnished on the shape of the cylinders. Whether they are L-head, with valves all on one side, T-head with valves on opposite sides or I-head carrying the valves in the head is part of the data supplied. The exact location of the valves is further told by a column devoted

ABBREVIATIONS:—Valve Location: Side and head, S & H.; Left and right, L & R. **Camshaft Drive:** Helical gears, Hel'l.; Spur gears, Spur. **Cooling Circulation:** Thermo-syphon, Thermo. **Lubrication System:** Splash and pressure, Spl-Pres.; Pressure, Pres. **Type of Pump:** Flywheel, Flwhl.; Rotary, Rot.; Centrifugal, Cent. **Ignition System:** Double, Doub.; Two-point, 2-Pt. **Ignition Make:** Westinghouse, Wsthse.; Atwater Kent, At Kent.; Connecticut, Conn. **Ignition Control:** Automatic, Auto.; Hand and automatic, H&A.; Hand or fixed, H or F. **Make of Carbureter:** Optional, Opt. **Fuel Feed:** Pressure-gravity, Pres.-Gr. **Type of Cranking System:** Electric, Elec.; Electric and air, E. & Air.

*60-inch tread optional. **Tread more or less than standard except Scripps-Booth, which is optional.

with Their Principal Specifications

specifically to that purpose. Another shows camshaft drive.

The systems of the car are next considered. These are the means for cooling, lubrication, ignition, carburetion, cranking, lighting and transmission.

The systems used for cooling the car are divided into three classes: those in which the water circulation is accomplished by thermo-syphon, those in which a pump is used and motors cooled by air. In describing the method of lubrication, the motor alone is referred to. Where all the bearings are taken care of by the oil that is splashed up by the connecting-rods, the system is known as the splash. Where the oil is forced by pressure to all the bearing surfaces, generally by way of the main bearings and thence through the hollow crankshaft to the connecting-rod lower ends after which it passes through a lead to the wristpin, the system is known as pressure feed. In the splash-pressure system a combination of the two methods is used. The oil is generally fed to the main bearings under pressure and thence flows into the splash troughs allowing the splash of the connecting rods to take care of the lubrication of the other bearings.

Under ignition, the type of the system is mentioned together with the make of the distributing or generating apparatus. The control of the spark whether it is fixed, hand or automatic, is stated. Describing carburetion the table mentions the make of the carbureter and the means for feeding the fuel. The question of whether or not a hot air pipe is fitted in order to aid in the best possible evaporation of the fuel is also answered. The name of the maker of the lighting and starting systems is furnished.

The Transmission System

In taking up the transmission system the drive is traced from the motor to the rear axle. The first unit, the clutch, is divided into the broad classifications of disk, cone or band. The type of gearset and its location together with the number of forward speeds gives full information on this point. The rear system is described giving the type of final drive, whether it is through bevel gears, spiral-bevel or worm, how the propulsive thrusts of the rear wheels are delivered and the design of the rear axle stating whether floating or otherwise. The information on the drive of the car is completed by stating the gear ratio and by furnishing a description of the running gear, stating the wheelbase, tire size and material from which the wheels are made.

The remainder of the table is devoted to information on the rear spring suspension, location of the drive and control members and a description of the type of bearings used for the crankshaft, gearset, rear axle and front wheels.

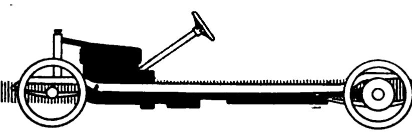
Engineering Development - 1915

Block-Cast Motors—L-Head Cylinders—Vacuum Feed Single Ignition—Better Equipment Are on the Roll of Honor for the Year 1915



TRENDS of design are vividly brought out by the announcements for 1915. On this and the following pages a review of the industry and the offerings of the manufacturers is furnished. On the whole the trends of last year are continued, and, in nearly every case, accentuated. The growth of the miniature car with its block-cast motor, its L-head cylinders with thermo-syphon cooling, single ignition, electric lighting and starting and full equipment, is the feature of the year.

¶ *Six-cylinder cars have not lost in the percentage tables in spite of the influx of new fours, but although the six retains its popularity, and is used in nearly as many chassis as the four, the car of 1915 has a smaller motor, a longer stroke bore ratio and a smaller piston displacement.*

¶ *Vacuum feed, the installation of starting and lighting systems on cars of extremely low price, the selling of sixes below $1,000, the increase in left drive and center control are high spots in the development for the new year. Fine equipment, both in upholstery and mechanical fittings on low-priced cars is another high spot, which the reading of the following short reviews will bring before the mind.*

Abbott Design Unaltered

Abbott has the same three cars that were offered last year, these being the 34-40, the smaller of the fours; the 44–50, the large four; and the Belle Isle Model 50–60, which is a six. The prices are unchanged.

The six a 3.75 by 5.25 motor with L cylinders cast in threes employes splash lubrication, Bosch ignition, pressure fuel feed to a Zenith carbureter and electric cranking and lighting. Other details include dry-disk clutch, four-speed gearset in unit with the engine and floating axle of 4 to 1 ratio. Left drive and center control are used, and tires are 35 by 4 1-2 on Firestone demountable rims, although wire wheels are optional.

The larger four, has pair-cast cylinders of L-head form, 4 1-2 by 5 1-2 inches. The gearbox of three speeds is unit with the motor, and drive goes back through a disk clutch to a floating axle of 3 1-2 to 1 reduction. The car has 121-inch wheelbase, gravity feed to a Mayer carbureter, electric cranking and lighting and 36 by 4 1-2 tires on Booth demountable rims.

The smallest Abbott is equipped with a 4 1-8 by 5 1-4 motor of unit power plant type, incorporating gearbox and dry-plate clutch with it, as do the others. The cylinders are L-heads and cast in block. Like the other car, the fuel feed is by gravity to a Mayer carbureter and two-unit electric starting and lighting are fitted.—Abbott Motor Car Co., Detroit, Mich.

Allen Adds Small Four

Two models instead of one is the Allen offering. This car which had its inception in the 1914 season with a four-cylinder is continued without mechanical changes. It has now been augmented by a smaller chassis also fitted with a four-cylinder model.

On the larger car 35 by 4.5 tires with non-skids in the rear are now used instead of the 34 by 4. Two auxiliary seats have been fitted, making it a seven-passenger instead of five. These seats were furnished last year along with the larger tires at an extra price, but this year they are included in the purchase price. The body has been changed to bring it up-to-date and it is now a streamline form in conformity with standard practice in this particular.

On the smaller chassis a small-bore, long-stroke, 3.625 by 5-inch block cast motor is used. The valves are all on the right side. The motor has an exceedingly short overall length and is part of a unit power plant suspended at three points. The valves are 1.625 inches in diameter and are of cast iron electrically welded to carbon steel stems. The timing gears are helical and have a 1-inch face.

The motor is oiled by a constant-level splash system in which a pump of the plunger type mounted on the outside of the crankcase takes the oil from the reservoir and circulates it to the main bearings and thence to the splash troughs. Starting and lighting is accomplished by a 6-volt electric system which is capable of cranking the engine at 150 revolutions per minute and which can carry the full lamp load when acting as a generator at 12-miles per hour. Ignition is by battery and distributer.

The transmission system consists of a leather cone clutch, a sliding selective gearset providing three forward speeds, and a Weston-Mott floating axle. The control levers which are central and on the right of the driver are mounted directly on the housing of the gearbox. The wheels are 32-inches in diameter and carry 3.5 inch tires. The wheelbase is 110 inches and the rear springs three-quarter elliptic. The rounded radiator and streamline body are in conformity with the latest ideas in carriage work. This model is made in either touring or roadster bodies.—Allen Motor Co., Fostoria, O.

Apperson Changes Cylinder Design

Two entirely new cars, one a four and the other a six, have been added to the Apperson line. This brings the number of models to four, two fours and two sixes. The new cars are similar in design although the motor dimensions and wheelbases are different. The new four model 4-40, has a 116-inch wheelbase and a 4 by 5 power plant with L-head block cylinders. It sells for $1,350. The new six at $1,485 and known as model 6-45 has a 3.5 by 5.125 motor, also L-head cylinders in a single casting.

Both cars incorporate many features of design new to Apperson practice. In the motor the air entering the carbureter is preheated by passing through a core in the cylinder casting. Another unique feature is that the casting which acts as a water outlet at the top of the cylinders, is double. Baffle plates and partitions are so arranged in the water passages on the four that the water flows up on one side and down on the other, giving a complete circulation. On the six the water is conducted along a space on the top of the cylinders until it reaches the rear of the motor where it passes a horizontal partition and flows back to the forward end.

The frame is narrower at the forward end giving a more rigid motor support and also providing a shorter turning radius. Force feed lubrication is continued, but there are independent leads to the camshaft bearings instead of splash.

In the structural work of the chassis, some slight changes will be noted, tending to lightening and simplifying. The transverse shaft which carries the brake and clutch pedals is now only one-half its former length. The rear support of the gearbox is the same as in the past and the drive members from that point back are much the same, except that in the new cars the drive is taken through the springs. The spring hangers are new, being in the case of the rear support integral with the frame gusset plates in the rear and of the strong ribbed section. The torque is taken through the rear springs which are underslung on the two new models. The Bijur lighting and starting system is regular equipment.

No change has been made in the contracting-band clutch which has formed a part of Apperson construction for several years. There are two universal joints in the drive.

The bodies supplied are of molded design with a rounded V-type radiator fitted with a distinctive shield.—Apperson Bros. Automobile Co., Kokomo, Ind.

Arbenz Improves Equipment

With the exception of such minor details as the shape of the lamps and windshields the Arbenz car will remain the same as for 1914. The line will consist of a four-cylinder chassis upon which two bodies are mounted, one a five-passenger touring and the other a two-passenger roadster.

Both these cars are mounted on a 120-inch wheelbase. The power plant is a 4.125 by 5.5 L-head, with its cylinders cast in pairs. The valves are all located on the left side and are operated by a helical gear driven camshaft. The transverse shaft, across the front end of the motor carries the magneto and water pump. The crankshaft is carried on three main bearings bushed with bronze. A dual system of ignition is used and electric lighting and starting made up of a Diehl motor, a Wells generator and a Philadelphia storage battery. The system operates at 6 volts and the battery has a capacity of 120-ampere hours.

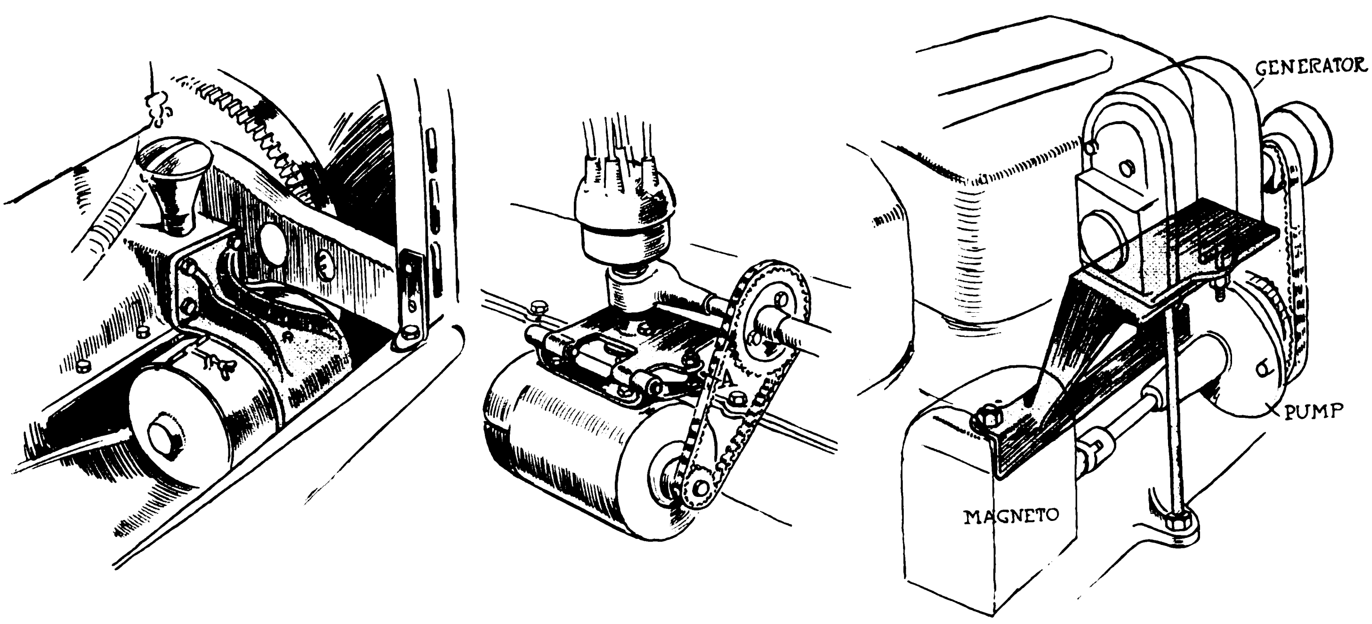
A 15-gallon gasoline tank located under the front seat supplies fuel by gravity to a Schebler carbureter. The transmission system comprises a leather faced cone clutch housed in the flywheel, a three-speed selected gearset carried in a unit with the rear axle and a beveled gear floating rear axle. The tires are 36 by 4 all around fully equipped with demountable rims.—Arbenz Car Co., Chillicothe, Ohio.

Argo a New Light Four

The Argo, a new small car of the year sells for $295, top and windshield being $20 extra. It comes as a roadster seating two side by side. The tread is 44 inches and the wheelbase 90.

The motor, a four-cylinder, water-cooled type, has cylinders, 2 5-16 by 4, cast in an L-shaped block. From the motor, drive goes through a cone clutch of internal type and thence to a gearset affording two speeds.

The propeller shaft carries a universal back of the gearbox and then enters a torsion tube which attaches to the



Some methods of mounting electrical units. Left—Showing how the starting motor is hung on a special bracket at the side of the crankcase on the Jeffery six. axle housing in the usual manner. The rear axle has a ratio of 4 to 1. Elliptic springs are used in front and rear.

Wire wheels with 28-inch tires are fitted, and oil side and tail lamps, horn and tools are included as regular equipment. —Argo Motor Co., 7 East Forty-second street, New York City.

Auburn Reduces Motor Sizes

The Auburn program for 1915 continues the manufacture of a four and a six as during the previous season, but these are so altered that they may really be regarded as new models. In addition, very material price reductions have been made. Model 4–36, the four-cylinder, sells at $1,075, either as a touring car or roadster, and is $415 cheaper as a roadster and $515 as a touring car. Corresponding reductions in the six model 6–40 which now is offered in either body type at $1,550, have been made, the previous six being a $2,100 touring car and $2,000 roadster.

In the six, the 3 3-4 by 5 1-4 engine has given way to a 3 1-2 by 5 1-4, L-head block-cast type with gearset in unit and suspension at three points in the chassis. The four continues to have a T-head motor, but it is a 3 3-4 by 5 in place of the formerly-used 4 1-2 by 5. Like the six, it is a unit power plant with three-point suspension.

Both cars are equipped with electric lighting and cranking, that of the six being provided by a Delco unit, while the four uses Remy apparatus. Carbureters are Rayfields, and fuel feed by the popular Stewart-vacuum system which draws the gasoline from 18-gallon rear tanks on both models. Cone clutches and three-speed selective gearsets are also incorporated in the chassis design.

The steering is on the left and control in the center. There is some difference in the drive features of the two models. The 6–40 has a double-universal open drive shaft with torque arm for drive and torque, and this operates a floating rear axle. In the four-cylinder construction, a three-quarter floating axle gets its power from a shaft having one universal, and drive is through the springs with torque on the universal.

Suspension of the cars is the same, the rear springs being three-quarter elliptic. The six has a wheelbase of 126 inches, and uses 34 by 4 front and rear tires on demountable rims. The four is a 114-inch wheelbased car, and runs on 32 by 4 tires also mounted on demountable rims.

The bodies are brought up to latest design of streamline appearance, and fenders are crowned. These are easily the most attractive cars the maker, the Auburn Automobile Co., Auburn, Ind., has ever turned out.—Auburn Automobile Co., Auburn, Indiana.

Austin Uses Double Cantilever

Model 66 Austin, with 4 1-2 by 6, six-cylinder motor and 141-inch wheelbase, is continued with a number of mechanical and body changes and a price reduction from $4,000 to $3,600. Touring, close-coupled and roadster bodies are fitted to the chassis, and much weight has been cut from the construction as compared with the 1914 cars.

An innovation is the use of double cantilever rear springs. On either side of the frame there are two light cantilever springs, attached at their centers to the frame bracket and shackling at their front ends to the frame, while the upper one attaches above the axle at the rear and the lower one below it. With this construction, two sets of torsion rods and four driving rods are provided. Easier and softer riding action is claimed for this design, for instead of supporting all the car weight of one side on one stiffer and heavier spring, two lighter springs carry it. The factor of safety is also pointed out to be much greater, because since the car weight is supported at four different points, if any one of the springs should be broken, there would still be three-quarters of the spring capacity on that side. This would be sufficient to continue any drive to its destination, though, of course, more care would have to be taken.

The Austin two-speed axle is used, but it has been redesigned and considerably lightened. One decided point of weight saving is an aluminum housing.

The motor is unchanged. It is a T-head block with a Westinghouse combination cranking, lighting and ignition set. The fuel system embodies a Master carbureter fed from a Stewart vacuum tank, the main reservoir of 25 gallons capacity being amidships under the frame. Other specifications are multiple-disk clutch in oil, left drive, center control of three-speed gear set mounted on the frame, and 34 by 4 1-2 straight side tires.

The close coupled body is new. Placed on the long wheelbase of 141 inches, the passengers are well forward of the axle. Tires and luggage compartments are placed directly over the axle.—Austin Automobile Co., Grand Rapids, Michigan.

Briscoe Remains Unaltered

Originally designed in France and brought to this country about a year ago by Benjamin Briscoe, the Briscoe car is continued with no change. The prices have been reduced from $900 to $785 for both roadster and touring with electric lighting and cranking.

The most distinctive feature is the single headlight in the radiator. Wire wheels, low-hung frame and general sloping of the body to the front aid in giving a light appearance. The wheelbase is 107 inches and tread 56.

The motor 3 1-8 by 5 1-8, of L-head design, has the cylinders and upper part of crankcase cast integrally, and uses detachable heads. The drive of camshaft and magneto is by a silent chain running over sprockets on crankshaft, camshaft and magneto shaft, and at the rear of the cylinders as distinguished from the usual forward location. Another unusual point is the casting together of intake and exhaust manifold, the exhaust gas passages being above the intakes.

The Aplco motor-generator is used for cranking and lighting, being driven through silent chain from the main drive shaft between the clutch and gearbox. The unit is placed to the left of the gearbox, and the ratio between electric unit and its driving shaft is 2 1-2 to 1.

Drive to the rear is through a drive shaft enclosed in a torsion tube, to a floating axle, which has a standard gear ratio of 3 3-4 to 1, with 4 to 1 optional. Semi-elliptic springs are used all around.

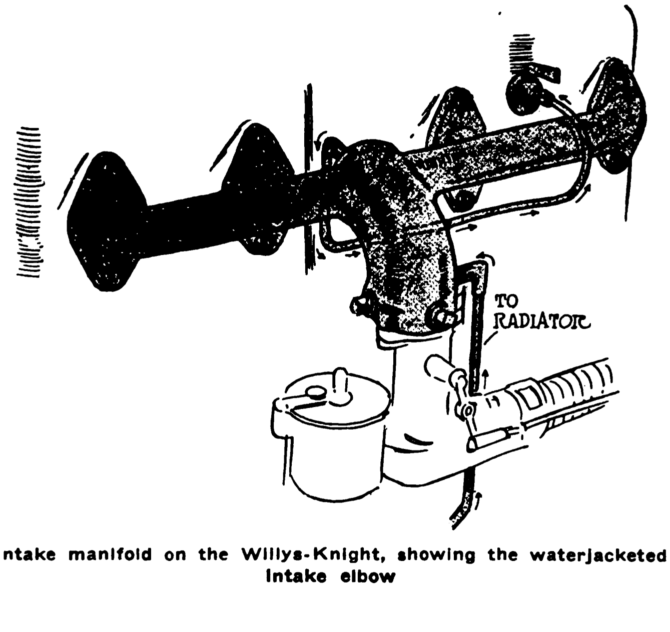
The bodies are well designed, the roadster seating being clover-leaf form, with accommodations for three by placing the center seat a little back of the two side seats. A coupe is designed similarly to the roadster.—Briscoe Motor Car Co., Jackson, Michigan.

Buick Adopts Vacuum Feed

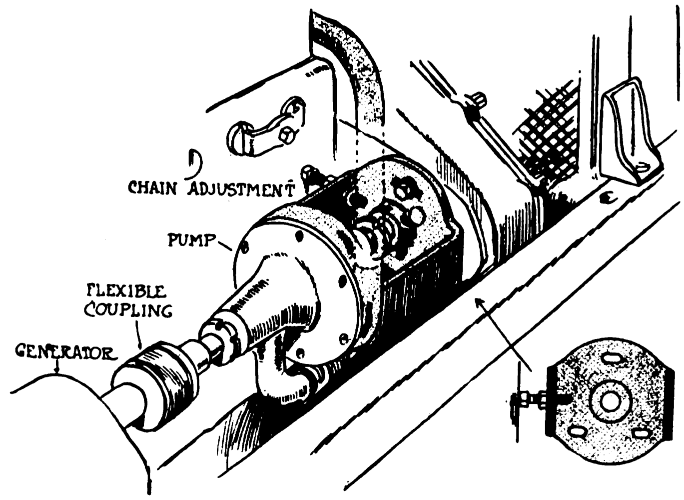
All Buick models are refined continuations. There are six four-cylinders and a six, which are built upon three chassis, and every machine has come in for some price reduction. The largest cut is the six from $1,985 to $1,650, while both large four-cylinder touring car, model C-37, and small touring, model C-25, have been reduced $100 to $1,235 and $950, respectively. The two roadsters, models C-36 and C-24, have been each cut $50, making their present prices $900 and $1,185, respectively. On each chassis a roadster and touring body is fitted.

The bodies are all newly designed, and radiators have been rounded at the top. Cowl boards are added to the fours, the six having this feature last season.

All Buicks use the valve-in-the-head motor. The six and the larger fours have 3 3-4 by 5 motors, and the small fours 3 3-4 by 3 3-4. Cylinders are in pairs. Tungsten steel valves have replaced nickel steel ones, and multiple steel piston



Intake manifold on the Willys-Knight, showing the waterjacketed intake elbow



On the Lewis six the water pump is carried on a bracket provided with adjustment for the chain drive by means of a bolt bearing against the side of the crankcase. The insert at the right shows the slots for the holding-down bolts in the base of the bracket

rings are used in place of individual rings in each groove. Pistons are longer to give a greater bearing surface and to eliminate any possibilities of piston slap.

Buicks use the Delco system, and a special feature in connection with it is the complete inclosure of all wires within conduits so that the wiring is now not only more substantially and neatly arranged, but it is proof against all conditions.

On the larger four-cylinder cars and the six, the Stewart vacuum system of gasoline feed is employed, with the vacuum tank located on the intake manifolds. The supply tanks remain at the rear. The small fours do not have this system. Another difference between these smaller cars and the others is that the gearset is not in unit with the motor in the former.

Wheelbase of the small fours has been increased 1 inch to 106 inches; that of the six is 130 and of the other fours 112. —Buick Motor Co., Flint, Michigan.

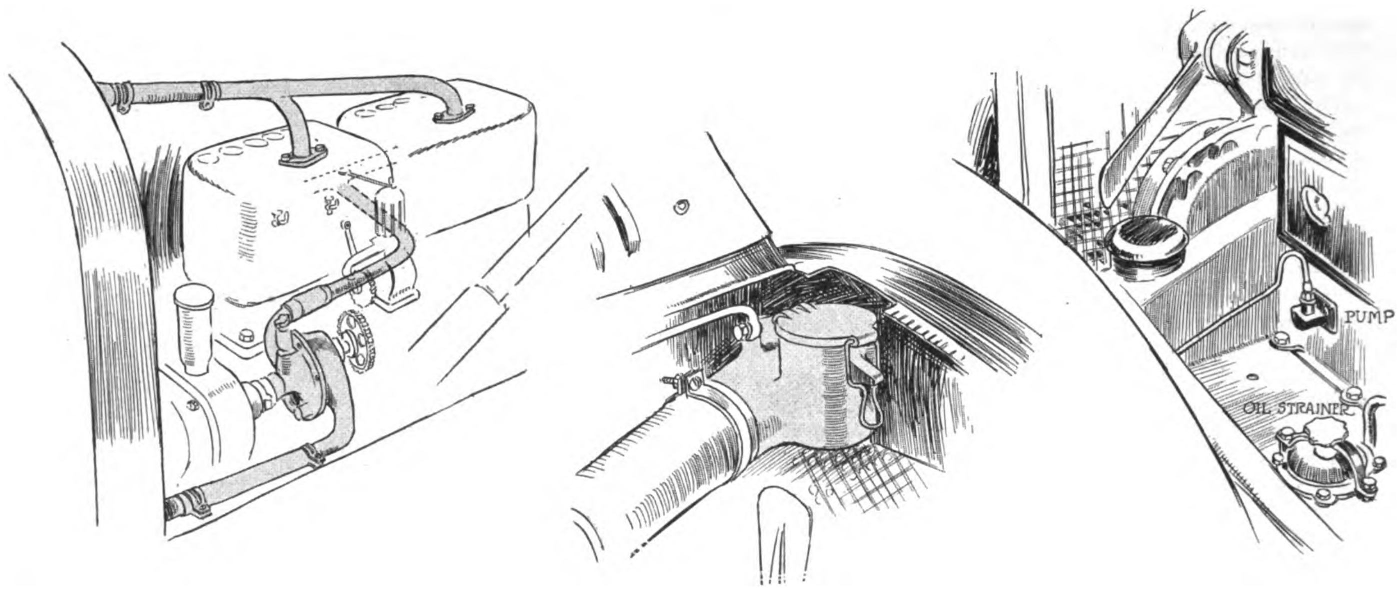
Cadillac Brings Out an Eight

Cadillac has the distinction of being the first American maker to market a motor of eight cylinders, and is equipping its chassis with this type of engine exclusively. In addition to the radical change to a 3 1-8 by 5 1-8, high-speed, V-type eight, the Cadillac chassis has other alterations as follows: The right drive and control have given way to left steer and center control, though the hinged steering wheel is retained. Wheelbase has been lengthened 2 inches to 122 inches, and the gearset, which was formerly located amidships of the chassis, is now made a unit with the motor. A disk clutch has replaced the cone type. In the rear axle, spiral-bevel gears are now fitted in place of the straight bevels used before, this change necessitating much reorganizing of the gear-cutting department of the Cadillac shops, and entailing the expenditure for some complicated machinery for the generation of the new gears.

Delco dual ignition, lighting and starting are still employed, and in most other respects the design is the same as in the past. Outward body appearance is little different than in 1914, though the bonnet, of practically the same length as heretofore, covers twice as many cylinders.

The Cadillac motor, which has created much interest among the motoring public, is said to be slightly lighter than the old four, due to the large reduction in weight of reciprocating parts and to the generous use of aluminum in the crankcase. The power curve shows that the engine develops its maximum of 70 horsepower at 2,400 r.p.m.

In the arrangement of the motor, the two sets of four cylinders are block cast and look like any block of four. They bolt to the crankcase, which is common to both sets,



Left—Water circulating system on the Pullman 6-48. Center—Filler cap under the hood of the Regal. Right—Side of Chalmers engine, showing shelf and accessible location of oil strainer and pressure pump

and their center lines are at an angle of 90 degrees to one another. Only one crankshaft is required, this being the same in design as a four-cylinder motor would use. The two connecting rod ends of opposite cylinders attach to the same bearing, one rod having a yoke end and the other rod going between the arms of this yoke. The two arms of the yoke are pinned to the bushing, which has its bearing against the shaft. The inner rod is free to move on this bushing, having its bearing on the outer surface of the latter. Only one camshaft is required, this being carried on a plate attached to the top of the crankcase. There are only eight cams, one cam operating two opposite valves through rocker arms attached to the same plate as the camshaft. Silent chains drive camshaft and Delco unit shaft, which is vertically above the other shafting and between the two sets of cylinders. At the rear end of the Delco unit are the gears for meshing with the flywheel for starting. The carbureter is also carried between the cylinder blocks, a U-shaped manifold running from it to the castings. An elaborate system of force feed oiling is used, the webs of the crankshaft being drilled and connecting with a supply pipe running along the inside of the crankcase. Another supply pipe carries oil to the camshaft bearings.

Thermostatic regulation of the cooling water temperature is another new thing to motor cars which Cadillac has adopted. By this arrangement, the water in the radiator is cut off when the temperature is low, causing only that in the jackets to circulate until the temperature rises, when a valve automatically opens the radiator supply. When the radiator supply is cut off, the water by-passes through the carbureter jacket, thus heating the carbureter quickly for starting. The temperature of the carbureter water governs the action of the thermostat.

Cadillac offers several closed types of bodies, namely, Sedan, limousine, phaeton, cabriolet and coupe on the regular chassis. These are examples of excellent coach work, and are at prices to correspond to the type of body.—Cadillac Motor Car Co., Detroit, Michigan.

Cartercar Increases Tire Size

Continuing the smaller of the two cars which were marketed for 1914, calling it model 9 instead of model 7, the Cartercar Co. has entered upon a year of one-model concentration. The model 5 of last year has been dropped entirely. This was a larger four.

Roadster and touring bodies have been redesigned and now have the popular sloping hood and cowl with smooth sided appearance. The friction drive system has had no change in design, though the copper transmission disk has been decreased 1 inch in diameter so as not to make any difference in reduction ratio between motor and rear wheels on account of the fitting of 33 by 4 tires as standard equipment instead of the 32 by 3 1-2 size which were fitted last year. The gear ratio in the rear axle has been lowered from 3.45 to 1 to 4 to 1.

The Cartercar uses a 3 1-2 by 5 four-cylinder Northway block motor, which has a detachable cylinder head. By increasing the clear opening of the valves from 1 11-16 inch to 1 13-16 inch, and by other slight differences in design, the power of the engine is made greater, the developed horsepower being 30 at 1,700 r.p.m. The construction of the engine is of the type with upper half of crankcase cast integrally with the cylinders, the flywheel being unenclosed. It is very similar to the conventional unit power plant construction but without a gearbox.

Delco combination ignition, lighting and cranking is used, the unit being driven off the end of the pumpshaft when a generator, and meshing with flywheel teeth when performing the cranking operation.

In the Cartercar drive system, the drive shaft from the engine connects to the transverse revolving transmission disk, 19 1-4 inches in diameter. Back of this and carried on a jackshaft is a fiber-faced friction wheel which revolves at right angles to the driving disk, and which is 21 1-4-inch diameter. A pedal pulls the driving disk away from the friction wheel so that the latter may be shifted into different positions with relation to the disk so as to give different speed ratios. An enclosed silent chain takes the power back from the jackshaft to the rear axle.

Steering and control are on the right, and wheelbase of model 9 is 106 inches. Equipment is complete, with demountable rims, windshield, top, electric horn, speedometer, tools and so on.—Cartercar Co., Pontiac, Michigan.

Case 5.5 Inches Longer

Continuing its three four-cylinder cars of last season with a number of improvements the Case T. M. Co., Racine, Wis., has reduced the prices of two cars and increased the price of one. The model 25, the leader, lists at $1,350 instead of $1,250; the 35 at $1,600, a drop of $250; and model 40 at $1,800, a reduction of $500.

The 35 and 40 are practically the same as in 1914, but the smaller car, the 25, has a wheelbase of 115 1-2 inches instead of 110, the tires increased from 32 by 4 to 34 by 4, the headlights equipped with double bulbs and the spark plug location shifted from the side in the valve plugs to the center of the cylinder casting in holes formerly occupied by the priming cocks. Battery ignition, using the accumulator of the Westinghouse cranking and lighting system, supplants the magneto used formerly. The brakes have been increased from 12 inches diameter to 14.

The Case company has discontinued buying its cylinder castings from an outside source, and for 1915 will do the work themselves. This applies also to the front axle, which is forged in the Case shops.

In the matter of body construction a few changes are noted. The lines have been changed completely in accordance with stream-line ideas, a foot rest is added to the tonneau, and in order to prevent the back of the front seat from becoming scratched a leather covering is provided. The improvement in body lines has allowed of a long cowl formed into a fuel tank, the container in the previous models being under the front seat. The feed, however, still is by gravity. A one-man top now is additional equipment.

The chassis of model 25 includes a four-cylinder, T-head, cast-in-pairs motor, 3 3-4 by 4 3-4, disk clutch and Brown Lipe three-speed gearset. The design of the 35 is the same as the 25; however the motor size is 4 1-4 by 5 1-2. The wheelbase is 120 inches.—J. I. Case T. M. Co., Racine, Wisconsin.

Chevrolet Increases Wheelbase

Two chassis, a four and a six, are offered for this year by the Chevrolet Motor Co., Flint, Mich. On the four, roadster and touring bodies are fitted, while the six carries only the touring type. The six, which is little altered from last year's car, a roomier body of attractive lines being the principal difference, is sold $50 cheaper than it was, the price now being $1,425.

With refined body lines bringing out the streamline effect, the fours have an increased wheelbase from 104 to 106 inches, while the brake drums have been enlarged 2 inches to a 12-inch diameter.

The six-cylinder motor is an L-head 3 5-16 by 5 1-4, with cylinders in blocks of three. Thermo-syphon cooling, constant level splash oiling, and Remy dual ignition are features of this power plant. The drive shaft is enclosed in a torsion tube, bolting at its rear end to the gearbox, the latter being in unit with the rear axle, which is three-quarter floating. Other specifications include cone clutch, platform rear spring suspension, left drive, center control and rear gasoline tank feeding by pressure.

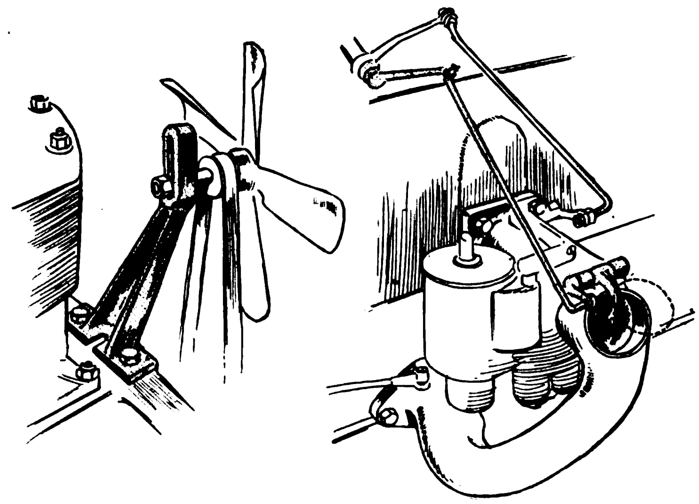
The wheelbase of the six is 112 inches, tires are 34 by 4 and Auto-Lite cranking and lighting are furnished at the price.

The fours have the distinctive Chevrolet motor with valves in the head, rockers and springs enclosed within an aluminum cover plate. Twenty-four horsepower is credited to the engine, whose dimensions are 3 11-16 by 4 inches. The cylinder head is a one-piece casting secured to the cylinder block by bolts, making a compact and readily removable assembly.

Drive is through a cone clutch to a three-speed gearset, located amidships on two frame cross members. Final drive is of the double universal unenclosed shaft type, torque being taken by a rod and drive by the rear springs, which are three-quarter elliptic. Tires are 32 by 3 1-2 on both roadster and touring car. The four-cylinder prices named do not include Auto-Lite electric cranking and lighting. When equipped with it, the price is $110 extra, five lamps and Prest-O-Lite tank being furnished at the above figures.—Chevrolet Motor Co., Flint, Michigan.

Chalmers Alters Gasoline Feed

Both the 1914 Chalmers sixes are continued this season. A number of detail refinements have been incorporated in both cars, and on the larger of the two, known as the Master



Left—Adjustable fan bracket on the Pullman Junior. Right—Application of vertical-flanged carbureter to Hupmobile. Also the new extra auxiliary air inlet with valve flap operated from dash

Six, a touring body of entirely new design has been fitted. The smaller chassis is known as the Light Six.

In fundamental features the cars are mechanically the same as for the past season, but some minor changes have been made. The cylinder dimensions are the same, but the core work has been altered to give greater water jacket space. The gasoline feed system has been altered to a combination pressure and gravity feed, the gasoline being forced by pressure to a small tank on the dash and thence flowing by gravity. This arrangement has permitted a slight raising of the carbureter, giving better accessibility. The carbureter is now the latest water-jacketed model G Rayfield, and the intake manifold has more water-jacketing space than before. While the multiple disk clutch was used in previous cars it has been improved by alternating bronze and steel disks in place of all steel.

On the smaller six Timken bearings have been added to the front axle. Both axles on the Master Six have been weighted to aid in holding the car on the road. The speedometer drive on both sixes is now the inclosed Empico.

Equipment is now better than ever before. A new design top, which is a product of the Chalmers shops, is fitted, the storage battery is of improved design, better separators being used to eliminate buckling of the plates. A volt meter has been added to the equipment and a Yale lock fitted to the electric switches. On the smaller car the tires are larger, being 34 by 4.5 instead of 34 by 4.

Five bodies are listed on the smaller car and two on the Master Six. The seven-passenger touring car on the Master Six is an innovation in that it is a boat-line design. The price of the Light Six is $1,650, or $150 less than in 1914 for the five-passenger car.—Chalmers Motor Co., Detroit, Michigan.

Chandler Lightens Flywheel

Greater power, which is obtained by lightening the flywheel and pistons, and by better balance that admits of higher operative speed, is the feature of the Chandler of 1915. Though the bore and stroke of the engine remain at 3 3-8 by 5 inches, the power increase is said to amount to 10 per cent., the motor having a rating of 35 horsepower.

With this refined motor $190 has been clipped from the price, it now being $1,595 for either open car-touring type or roadster. These bodies are much the same in general appearance as they were, having the popular stream lines and sloping hood and sides. Besides these, an attractive line of closed bodies was brought out last fall, all fitted to the same six-cylinder chassis.

The Chandler company makes a strong point of the light weight of its car. To attain this end, the chassis is simple and parts made as light as possible consistent with their functions. The six cylinders are cast in L-head fashion in blocks of three, and a unit power plant is obtained by bolting the gearset with its center control to the flywheel housing. One change in the engine equipment is the adoption of Rayfield carbureter. Bosch ignition still is used, while a two-unit Westinghouse electric system for cranking and lighting is employed.

The Chandler chassis has a 120-inch wheelbase, and rear spring suspension is of the three-quarter elliptic type. The drive from the motor is by an uninclosed shaft fitted with two universals, and paralleled by a torsion arm of pressed steel. When first brought out the car had a torsion arm made of bar stock, but the pressed steel type is lighter.

The rear axle is of floating construction, conventionally designed. Tires are 34 by 4 all around, and demountable rims, in addition to electric horn, Jones speedometer, New Haven 8-day clock, Jiffy curtains and lesser items feature the equipment.—Chandler Motor Car Co., Cleveland, Ohio.

Cole Four Is Smaller

Three chassis, two sixes and a four, make up the Cole line. The four is a revised addition of the four of last season, having the same power plant but a chassis which has been shortened two inches in wheelbase and lightened throughout. At the same time the price of this car has been cut in the touring and roadster bodies from $1,925 to $1,485. The big six is the same as for last year in every particular, except that vacuum gasoline feed has been adopted, and the remaining six is a new addition to the line built along the plans of the small sixes which have made their appearance during the past year.

The six-50, which is the added six, has a 3.5 by 5 L-head unit power plant with three-point suspension. The valves are all carried on the left side and are operated from a single integral camshaft driven by helical gears. Both manifolds are separate castings, and the water is circulated by a centrifugal pump.

Lubrication of the motor is accomplished by a non-circulating splash system in which the oil is fed by gravity sufficiently rapidly to replace the lubricant consumed by the engine. The feed is arranged to be proportional to the throttle opening. Ignition, lighting and starting is accomplished by the Delco system, providing a dual ignition outfit, with dynamo, storage battery and dry cells, and a 6-volt lighting and starting system. The battery is an Exide, 120-ampere hour. Vacuum feed takes care of the gasoline, the 15-gallon tank being on the rear end of the chassis. The clutch is a cone within the flywheel, the gearbox a three-speed selective and the rear axle a Timken floating.

The new four, which is changed from the four of last season because it is lighter in weight, has a new streamline body, a Stromberg carbureter, vacuum gasoline feed and a new Timken equipment throughout. It has the 4.25 by 5.25 L-head power plant cast in pairs. The valves are on the left side. Many other features of the chassis are similar in design to the six. The Delco electric system cone clutch, etc., being common but the rear axle is semi-floating. The wheelbase of this car is 120 inches, as compared to 118 inches on the car of last season.—Cole Motor Car Co., Indianapolis, Ind.

Crawford Alters Suspension

But two changes have been made in the Crawford 4-40, which is continued for this season. This is a five-passenger touring model, and the changes have been, first, to alter the suspension of the motor from four-point to three-point, and, second, to divide the front seat in the body to permit the exit of passengers without disturbing the driver, and also allowing passengers to change from the rear to the front seat without leaving the car. The car will be built with right drive and will be fully equipped with lighting and starting.

In addition to the four, the Crawford company will market a light six, which will be an innovation for this season. It is equipped with a 3.5 by 5 motor, forming part of a unit power plant, a Brown-Lipe gearset and a Timken axle, with a full equipment of roller bearings. The body fitted to this car is of five-passenger capacity, streamline design, and is also provided with the aisle between the front seats as described in the four. This model is left drive and center control, and though a six-cylinder sells for $250 less than the four, being listed at $1,850.

The new six, which will be the leader of the line this season, is an adaptation of the up-to-date light-weight six-cylinder car. It has its L-head cylinder cast in a single block and the crankshaft carried on three main bearings. Both the pump and camshafts are driven by helical gears, and the lubrication is by a circulating splash system. For ignition there is a Bosch magneto, and for cooling a centrifugal pump and cellular radiator. The gasoline feed is by vacuum from a 20-gallon tank carried on the rear.

A multiple disk clutch delivers the power to a three-speed gearset, and the rear axle as well as the front are Timken products, fully equipped with tapered roller bearings. The body is of sheet metal over a wood frame.—Crawford Automobile Co., Hagerstown, Md.

Crow Adds a Four

An entirely new four-cylinder car has been added to the Crow line bringing this up to four models, three of which are fours, and one a six. The new car is the smallest of the three and is an entirely new design. The other two fours which are known as E-45 and E-55 are practically the same as for last season except that they are both furnished with streamline bodies and the E-45 now has full electrical equipment. The six is known as E-62.

The new car known as the Crow-Elkhart, Jr. has a 104-inch wheelbase and is provided with a five-passenger body of streamline contour. The motor is a compact design with the 3.125 by 4.5 L-head cylinders cast in a single block and having the crankcase, timing gearcase, water manifold and intake all of aluminum. A steel stamping is used for the bottom pan. The valves are on the left side and are completely inclosed. They have a diameter of 1.125 inch and a lift of .31 inch. The piston rings are a special non-leaking design and the timing gears have a helical pitch. The crankshaft is 1.625 inch in diameter with two bearings, the front having a length of 2.5 inches and the rear 3 inches. The center distances between the bearings are 14.75 inches.

Electric lighting and starting is by the U. S. L. or Huff systems. The generator is located on the left side of the motor and the starting motor on the right. Ignition is by the Connecticut and Briggs system with the distributer mounted on a vertical shaft at the rear of the motor.

A multiple-disk clutch of the dry-plate type in which engagement of the plates is secured by three coil springs, delivers the power to a three-speed gearbox which is integral with the rear axle. The gears and the gearbox are of chrome nickel steel and are carried on New Departure and Hyatt bearings. The rear axle is a floating design having a 2.25 inch housing with a heavy truss-rod. The pinion is a 20-point carbon steel bevel having a ratio of 4.125 to 1. Thirty by 3.5 tires are used on the wood wheels.

The E-45 has a 4 by 5 motor with the L-head cylinders cast in pairs. It has a disk-in-oil clutch, rear axle gearbox and full streamline body. The E-55 differs materially from the E-45 having its four cylinders in a single block. They are 4.25 by 5.5 with the valves on the right. Right drive with center control is used on the Crow models. The price of the Junior is $725. The six has a 3.75 by 5.5

motor and a 130-inch wheelbase.—Crow Motor Car Co., Elkhart, Ind.

Cunningham Adopts Disk Clutch

One chassis, which is a continuation of the car of last season, will be built by the Cunningham company. In continuing this model a few refinements have been made, one of which has been the substitution of a dry-plate disk clutch for the cone, a simplified brake system eliminating many of the parts of the linkage and a new series of body design.

Cunningham motor is a four-cylinder 4.75 by 5.75 valve-in-the-head. The cylinders are cast in pairs, with a removable head; the manifolds are separate castings. The motor is suspended at four points.

Oil is forced under pressure to the main bearings, but all other bearings surfaces are taken care of by the lubricant which is splashed from the connecting rods. A gear pump takes care of the circulation, bringing the oil from the reservoir which is in the lower half of the crankcase.

Ignition is by a dual system and carburetion by a Stromberg model G 1.5-inch size, with a water-jacketed mixing chamber and a hot-air pipe. Fuel feed is by pressure, the gasoline tank being under the rear end of the frame and having a capacity of 20 gallons. The electric starting and lighting system operates at six volts.

The clutch is a disk having steel to steel friction surfaces and being housed in the flywheel. The gearbox is in a unit with the motor and is of the selective type, having three speeds. A spiral bevel rear drive is used in connection with a floating axle. The wheelbase is 129 inches and the tires 37 by 5.—James Cunningham, Son & Co., Rochester, N. Y.

Cycleplane Continues a Two

Two chassis upon which there are mounted three body styles is the offering of the Cycleplane company. These two models are known, respectively, as the Tourist and Traveler. On the Tourist are two bodies, one a roadster of two-passenger capacity and the other a touring of three. On the Traveler, which is a two-cylinder car, there is only a tandem roadster of two-passenger capacity.

The four-cylinder model has its L-head cylinder cast in a single block. Valves are on the left and covered, providing the neat powerplant common to the block cast design. The two-cylinder model has its cylinders cast singly, one valve being on the left and the other in the head. Cooling on both cars is by thermo-syphon and oiling by splash. The only difference in the oiling systems is that due to the necessities of two and four-cylinder practice. Both pumps are of the plunger variety, circulating the oil to the main bearings and thence to the splash troughs, where it is picked up by the connecting rods. Both cars use single ignition, in the Tourist the make being optional, while in the Traveler the Atwater Kent, with automatic spark advance, is regular equipment.

The Cycleplane company is using its own make of carbureter for the four-cylinder car, while a Schebler motorcycle model is used on the two-cylinder. A selective gearset with three speeds is used on the four and the two has a planetary gearset with two speeds. Another difference in the drive is that the four is beveled gears while the two uses the chain. The wheelbases are, respectively, 108 and 96 inches, and the tires on the four are 28 by 3 while on the two they are 28 by 2 1-2.—Cycleplane, Westerly, R. I.

Detroiter Is Lengthened

While the four-cylinder Briggs-Detroiter is fundamentally the same as in 1914, a number of chassis and body improvements are noted. The 3 by 5, L-head, block motor and all the important chassis dimensions remain the same except the wheelbase, which has been increased from 104 to 112 inches. There is an entirely new design of body, in which the use of drop forgings in place of castings for the levers and other fittings, and a light one-man top greatly reduce the weight.

In appearance the car has been considerably altered, as it has now the round radiator, tapered hood and streamline flush-sided body. A mud shield is added to the bottom of the radiator and the rear appearance changed by removing the bracket from the rear platform spring perch and in its place supporting the spring directly from the rear frame torque member. The springs have had an extra leaf added to them.

It has been found possible to raise the carbureter 4 inches, due to placing the gasoline tank under the cowl. While the motor support is still a three-point scheme, there is now a full cross member to take the rear support and a new type of front member has been fitted which permits the motor to be lifted directly out of the frame. The starting motor bolts directly against the front of the motor, whereas last year it was held on a separate shelf. This year the starting and lighting outfit is a Westinghouse, although operating at the same voltage and with practically the same connection as the previous type.

An innovation is the use of an oil level warning light, which flashes when the oil level in the crankcase drops to a dangerous point.

The bodies are now roomier and 1.5 inches lower than before, the running boards free and the doors widened to 24 inches. The fenders are crowned.—Briggs-Detroiter Co., Detroit, Mich.

Dile a New Small Car

Another new car in the low-priced class is the Dile. It is made in one-body type only, a two-passenger roadster, with a four-cylinder 2.625 by 4 block power plant, dry-plate clutch, three-speed gearbox with shaft drive to a semi-floating rear axle. All the transmission parts and axle are mounted on annular ball bearings.

Everything has been done throughout this little car to keep the weight down and at the same time provide ample power and room for the two passengers. The valves are on the right, driven by an integral camshaft, which is operated from the timing gear case by spur gears. Cooling is accomplished by thermo-syphon and lubrication by a plunger pump which is operated from the camshaft. This pump circulates the oil to the main bearings, whence it flows to the splash troughs to meet the connecting rods. The splash takes care of the cylinders, camshaft bearings, etc.

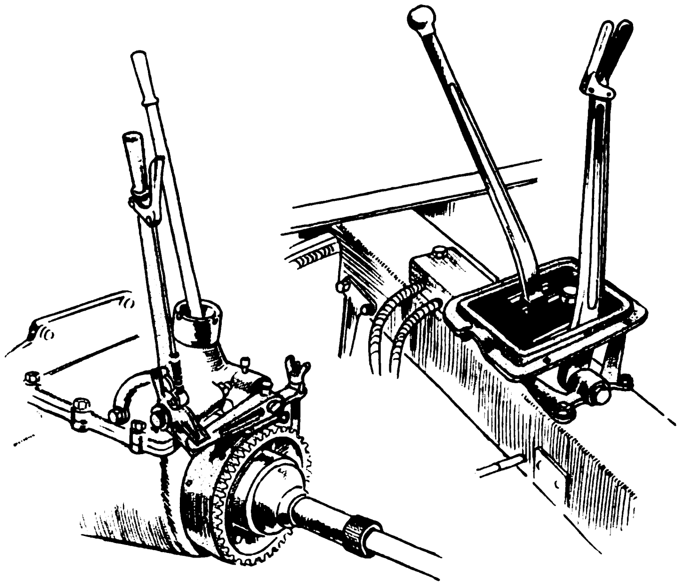
Ignition is by a single magneto system, the Berling high-tension instrument being used with fixed spark. The carbureter is a Holly and the gasoline tank of 5.5-gallons capacity, feeds by gravity from the dash. Electric starting is extra, but a Dyneto generator and Willard-Elba storage battery form part of the lighting equipment.

The dry-disk clutch is housed in the flywheel and has asbestos-against-steel driving faces. The three-speed gearset is selective and is mounted amidships. Control is in the center and the drive is on the left. The wheels are the Houk detachable wire design, and one set of the brakes is located on the rear pinion shaft of the differential and the other internal on the wheeldrum.—Dile Motor Car Co., Reading, Pa.

Dodge Has Improved Gearbox

The Dodge Bros. line was disclosed late in the fall by the announcement of a five-passenger machine of 110-inch wheelbase and equipped with a 3 7-8 by 4 1-2 motor. It can be had only in the one body type.

There is nothing unusual about the mechanical design of the car, although every detail has undergone careful testing before it was decided upon. One point of advantage is the provision in the gearset for shifting the countershaft driving gear out of mesh with the mainshaft gear when the drive is direct so that when the car is in high, the countershaft is not rotating.



Left—Emergency brake behind transmission on Lewis six. The speedometer drive is taken at this point. Right—Mounting of gate for levers on cross-member on the Studebaker

The specifications include the block-cast, L-head motor with gearbox in unit, North East cranking and lighting of single-unit type, Eisemann magneto ignition, cooling by centrifugal pump circulation, separate cylinder head held to the main casting by steel bolts, cone clutch, drive through propeller shaft enclosed in a torsion tube to a floating axle, three-quarter elliptic springs, overslung frame, left drive and center control.

Some of the equipment items are Jones speedometer, one-man top, rain vision and ventilating windshield, Willard battery, and 32 by 3 1-2 tires on demountable rims.

The intake passages are cored in the casting, extending from the single opening to the carbureter on the left to the intake ports on the other side, the cored passages being between cylinders Nos. 2 and 3. The exhaust manifold is a separate casting. The reciprocating parts are of standard design, although the use of thin steel piston rings, three to each ring groove, is specially notable.

The motor is oiled by a circulating splash arrangement, and the motor-generator, mounted on the left forward side of the engine, is of the 12-volt type driving through an inclosed silent chain from the crankshaft with a 3 to 1 reduction.

The floating axle has a pressed steel housing, and mounted on it are the brake shafts and equalizers, allowing the operating rods to run forward centrally of the frame. The latter is well-braced with three cross members, and carries a 15-gallon fuel tank at the rear. The feed is by pressure.—Dodge Bros., Detroit, Mich.

Dorris Adopts Vacuum Feed

One model, a four-cylinder, is the offering of the Dorris company for this season. This car, mounted on a 121-inch wheelbase is a direct continuation of the model marketed last year and is a result of 9 years' development by the Dorris Motor Car Co.

The four-cylinder overhead valve motor has its 4.375 by 5 cylinders cast in pairs. The Dorris dry plate clutch and fan flywheel are continued as features of the unit power plant in connection with the three speed gearbox used last season. Last year the clutch was considerably overhauled by adding a number of plates and using lighter springs. The gearbox remains the same as for the past three seasons with the exception that the levers are in a more accessible position, on account of having been moved forward slightly.

An alteration that is in line with the policy of several concerns this year, is the adoption of vacuum feed for the gasoline. Last season the gasoline feed was by pressure with the tank placed lengthwise of the chassis at the left side immediately under the body. The filler cap and gasoline gauges were then under the front floor boards. A cut in price from $2,500 to $2,200 in the five-passenger touring car body and from $2,550 to $2,250 for the seven-passenger touring is another change for this season. In body work an addition to the line is the Sedan. It is mounted on the same 121-inch wheelbase chassis as the other two cars.—Dorris Motor Car Co., St. Louis, Mo.

Empire Is Electrically Started

The same chassis as has distinguished the Empire line for the past 3 years is continued and with the same body as marketed last year for $900, can now be purchased for $850. But in addition to model 31-40, a five-passenger touring car has been added. A roadster which corresponds to the new touring car in equipment and general appearance is another addition.

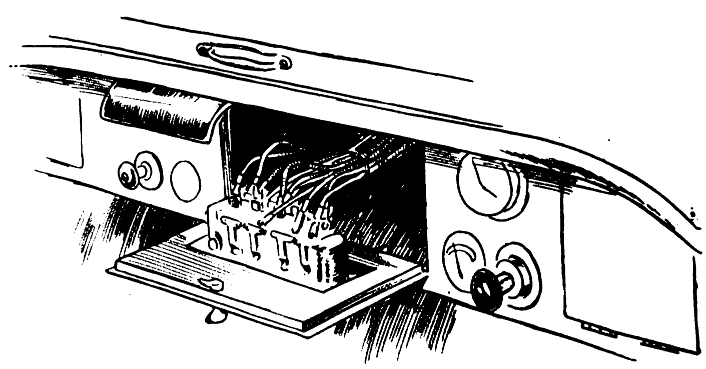
In bringing out the new chassis the most important change outside of the entirely new bodies is the adoption of the Remy lighting, starting and ignition system. The mounting has necessitated some small changes in the motor exterior although all the principal dimensions remain unaltered. The oiling pump is now a horizontal instead of a vertical design and an oil pressure chamber is integral with the pump in order to maintain a steady flow to each of the leads. A priming cup has been mounted on the oil pressure chamber so that in case the car has not been used for some time the proper working of the pump will be insured. Formerly the clutch adjustment was held by a number of steel plungers, but now it is permanently secured by bolts.

The new lighting, starting and ignition system is of special interest in that it is the latest Remy product and is a motor-generator outfit with battery ignition. The cylindrical motor-generator is carried on the forward end of the motor at the right. Its single armature with a compound winding operates 12 volts and performs the functions of the cranking motor and generator. The generator commences to charge at an engine speed of 350 r.p.m. and carries the lamp load at any speed above this with an output of 6 amperes.

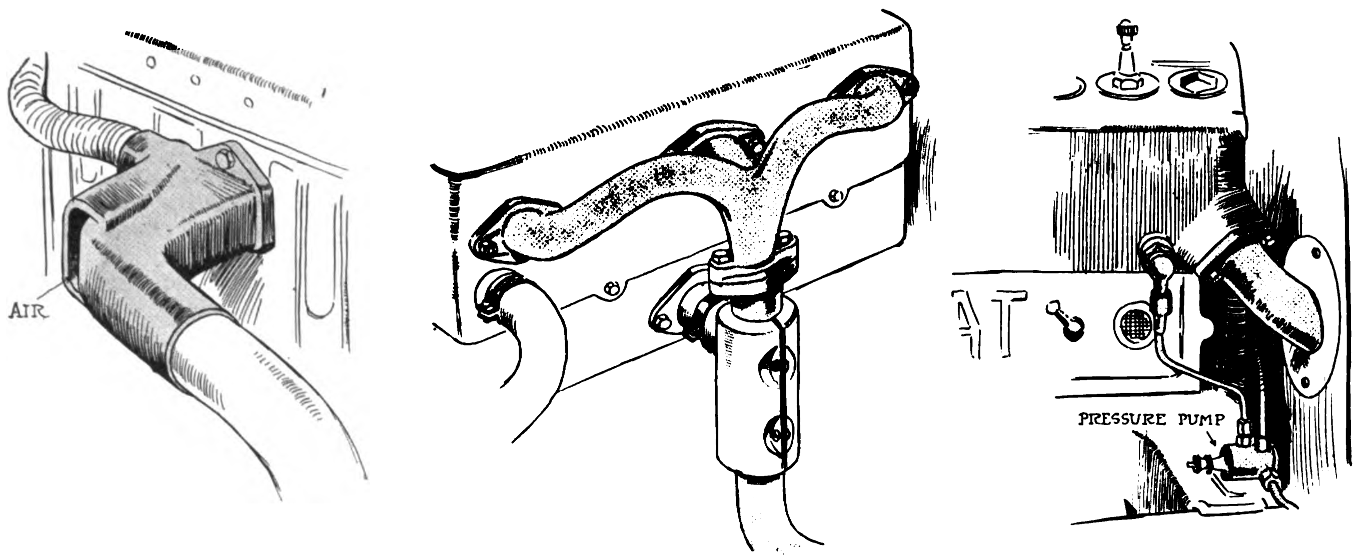
A choice of the touring car which was sold last year, equipped with acetylene lighting, and the new touring car with electric lighting and the streamline roadster is offered. The 3.75 by 4.5 power plants are used on all cars.—Empire Automobile Co., Indianapolis, Ind.

Enger a Unit Power Plant

A six-cylinder chassis with 124-inch wheelbase is the offering of the Enger Motor Car Co. On this is fitted a streamline body with a six- or seven-passenger capacity and clean cut exterior without any luggage being carried upon the running board.



Hinged switchboard on dash of Locomobile Small Four, which exposes all connections in accessible position



Left—Hot-air intake cast integral with exhaust elbow on Chevrolet. Center—Special shaped exhaust manifold on new Hupmobile, showing hot-air stove on exhaust pipe. Right—Short exhaust elbow and location of pressure pump on Fiat

The Continental L-head block power plant is used. The valves are on the right, together with the pump and generator shaft from which the Atwater-Kent distributer is driven by a bevel gear. On the right side of the motor is the carbureter and cranking motor which engages with teeth on the flywheel. The carbureter is fitted with a dash adjustment for easy starting and is water-jacketed. The oil breather and filler opening is also on this side of the motor, and there is also a gauge for determining the oil level.

Connection between the motor and gearset is made through a multiple disk clutch housed in the flywheel which is inclosed in a bell-shaped extension of the crankcase to which is bolted the gearbox. Three speeds are provided by the gearset, the lever being mounted directly on the top of the housing in accordance with general practice for central control. Two universal joints are used in the drive and no torque or radius rods are provided, the functions of these being performed by the spring. In order to stiffen the springs sufficiently for their dual service in suspension and torque transmission the main leaves are constructed from vanadium steel.

In body work the streamline form has been adhered to. The seating arrangement is provided by the ordinary front and tonneau seats with two auxiliary seats which fold in the rear. The slope of the cowl is unbroken as the side lights are not used. A dimming arrangement in the head lamps provides signal lights.—Enger Motor Car Co., Cincinnati, Ohio.

Fiat Alters Bodies Only

The only changes made in the Fiat car are those affecting the body style. The cowl will have a greater curvature making a small dash which harmonizes with the general lines of the car. Multiple bulb headlamps will be used, eliminating the side lamps.

There are three models of Fiat known respectively as 54, 55, 56. The first two of these are four-cylinder types and the third is a six. The Fiat design is distinguished by the fact that the motors are all of the block type, even the six having a very short overall length. The Fiat company manufactures on the metric system and consequently the bore and strokes of their motors are in millimeters but translated to inches are 4.4 by 6 and 5.12 by 6.75 for the fours and the six has the same bore and stroke as the smaller four.

The cylinders are all L-head carrying the valves on the left side. The manifolds are cast integrally with the cylinders, the result being a motor of small dimensions and clean exterior appearance. Helical gears are used on all the models to drive the camshaft while the magneto, water pump, etc., are operated from a transverse shaft.

Pressure feed lubrication is used, the oil being circulated by a gear pump. Water circulation is maintanied by a centrifugal pump, the remaining part of the cooling system being made up by ample waterjackets in connection with a honeycomb radiator. The fan is formed by the pitched blades of the flywheel.

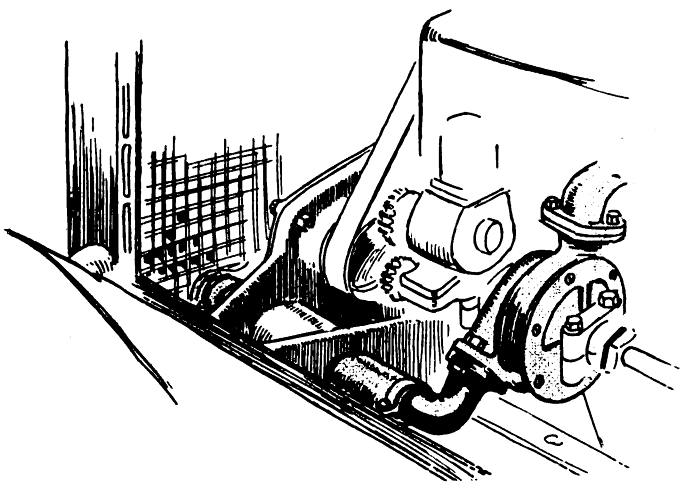
Ignition is accomplished by the Bosch dual system and starting and lighting by Westinghouse in connection with a Willard storage battery. In transmitting the drive disk-in-oil clutches are used, the friction faces being steel to steel and the housing being within the flywheel. All models have four-speed gearboxes with direct on fourth and all have a rather high gear ratio, the lowest being in the six, where a ratio of 3.06 to 1 is used. A feature of Fiat construction is the pressed steel rear axle housing which eliminates both radius and torque rods, being continuous to a forked yoke which connects with the gearbox.—Fiat Automobile Co., Poughkeepsie, N. Y.

Firestone-Columbus Drops Four

One four and one six are listed by Firestone-Columbus this season. The larger four of last year, which was only fitted on a raceabout body, has been discontinued. The bore and stroke of the four and six which are made for this season are the same, being 4.125 by 5.25. The four-cylinder motor has the cylinders cast in a single block while on the six they are in two groups of threes. Both have L-heads with the valves on the left side.

Last season, only the six-cylinder model was equipped with the Gray & Davis lighting and starting system but this year the four has also been fitted with it. A difference in the electrical equipment, however, which has been maintained, is in the ignition. On the four, the Splitdorf Dual system is employed, while on the six, the Connecticut outfit forms a part of the double system. The carbureter on the four is a Schebler while on the six it is a Rayfield. The Schebler carbureter is not equipped with hot-air pipe while on the Rayfield this equipment is used. The feed of gasoline is accomplished by gravity on both models.

Differences between the construction of the four and six are noticeable also throughout the drive, while the four has a cone clutch, amidship gearbox, without the unit power plant feature, the six has a disk clutch and a unit power plant in which the three-speed gearbox is incorporated in the same housing as the clutch. This being a bell-shaped casing



The rubber connection between the pump and the radiator on the National six passes through a hole cast in the crankcase arm

which is a continuation of the crankcase. Both the six and four have bevel final drive to a floating axle. The wheelbases of the two cars are respectively 116 and 132 for the four and six and the tires 34 by 4 and 36 by 4.5. The six-cylinder car has smaller tires in the front than in the rear, 36 by 4 serving for this purose.

In body work the four is made up in a roadster and touring while the six can be had in either five-passenger touring or seven-passenger touring.—Columbus Buggy Co., Columbus, O.

Ford Adds Two New Bodies

Ford continues the familiar model T chassis, although bodies have been redesigned. Last October, two new body types were added, a coupélet and a sedan, swelling the line to five types. The others are the roadster, touring car and the town car.

The coupélet may have the top folded back when weather permits, but it may also be closed so that no water or snow can get in. It is then virtually a coupé. The upholstering is deep and windows wide in sliding sash. The sedan has two wide doors, and provides seating for five, three in the rear seat and two in front on individual chair type seats. The right hand seat is on a pivot and folds back out of the way. Wide window panels make for clear vision in all directions.

The model T chassis with 100-inch wheelbase carries a 3 3-4 by 4, block, L-head motor cooled by thermo-syphon. This engine is three-point suspended in the frame, and a feature is the flywheel magneto, which provides the ignition current. Planetary transmission is employed which gives two forward speeds and reverse. The drive shaft is enclosed with a torsion tube which is a unit with the rear axle housing. The clutch is a steel disk design, brakes are on transmission and rear wheels, the former being the service set. Semi-elliptic cross springs are used front and rear, shackling at their ends to the axles. The front tires are 30 by 3, and the rear 30 by 3 1-2.—Ford Motor Co., Detroit, Mich.

Franklin Adopts Spiral Bevel

Franklin prices are reduced. On the touring car at $2,150, $150 has been taken off and a similar amount from that of the roadster, while on the closed cars a still greater reduction has been made, $200 in the Berlin and Sedan and $350 on the coupé.

Mechanically only one change is made on the motor and that in the fitting of the oil adjustment on the cowl board instead of under the hood. In the starting and lighting system better accessibility is obtained and by an improvement in the Dyneto commutator and brushes; this system weighs 40 pounds less than formerly. In the rear axle spiral bevel gears have been adopted in place of the straight bevel. A number of small details such as the spring pivot bolts, the front springs, magneto attachment, etc., have been revamped. The magneto is now attached by two dowel pins, and a divided metal strap over the top in place of the bolted-on brackets. In the front spring the deflection was 1 inch to 180 pounds, it is now 1 inch to 200 pounds. In the spring pivot bolts a new bushing has been employed which incorporates a felt washer intended to keep the dirt out and the oil in.

Better equipment at the lower price is the result of increased production efficiency in the Franklin plant. This season either the Goodrich Silvertown cord tires, or the Goodyear Power-Saver cord type are offered as regular equipment. The Hartford single-cylinder tire pump is fitted. This, together with the bracket which supports it, weighs 6.5 pounds. By the use of this pump the Franklin company claims to have removed the reason for the heavier type of demountable rim and now substitutes the Q. D. type.

In body work the front doors are wider and set back a little to permit of easier entrance. Mud guards are wider and the rivets are invisible. Side lights have been eliminated. The Franklin is one of the few cars which fits a luggage carrier as regular equipment.—H. H. Franklin Mfg. Co., Syracuse, N. Y.

F. R. P. a High-Speed Design

A new speed creation has been brought out under the name of F. R. P., by Finley R. Porter, ex-chief engineer, of the Mercer company. It is made up only in chassis form and without a body sells for $5,000. The chassis is a study in the use of alloy steel. The 4.6 by 6.75 I-head motor is fitted with camshafts, crankshafts and connecting rods of hollow chrome vanadium steel and throughout the car this alloy has been employed to give the utmost lightness with the greatest possible srength. Magnalium, an aluminum-magnesium alloy has been employed for housings.

The motor is a different design from any heretofore employed in American practice. It has its four cylinders cast in a block and is provided with an overhead camshaft which is driven by a worm and vertical shaft at the front end of the motor. The valves are the 45-degree poppet type, but are so formed that when they are closed the combustion chamber is practically a hemisphere. In every other particular, with the exception of double, 80-pound valve spring, the design does not depart from ordinary valve-in-head practice to any marked degree.

An unusual oil pump which has a capacity of 30 pounds at 1,500 r.p.m. and which has an ultimate capacity of 600 pounds is used. The pump is a rotary piston design operated by two cams located at the bottom end of the vertical shaft which drives the camshaft.

The clutch is a cone housed within the flywheel. The latter is 21 inches in diameter and is a steel forging providing a clutch surface 19 inches in diameter and 2.5 inches face width. There is a compensating joint between the clutch and the gearbox which provides four speeds. The shaft is a hollow member and takes the drive through two universal joints to a bevel gear differential. Chrome vanadium gears are used here and the driving stress is transmitted through the springs.

For service purposes there is a brake on the shaft and the emergency is carried on the rear wheels. The steering gear is a worm and full gear with a magnalium housing a 2-inch post. The complete electric equipment is made by Bosch and the wheelbase is optional to suit the style of body ordered.—Finley Robinson Porter Co., Port Jefferson, L. I.

Glide Has Dash Control

The four-cylinder Glide has received changes affecting the body, carbureter, clutch, brakes, windshield and carbureter air control. The tonneau seat has been made wider and the braking system entirely redesigned. It now consists of a two-piece, brake-operating shaft extending from one drum to the other and being split near the middle, the abutting ends each having an operating lever. The two levers are clamped together and one of them is connected by a rod to the brake pedal. This system is said to give the advantages of brake equalizers and preventing one brake from refusing to work at the same time giving simultaneous adjustment.

A knurled button in the center of the steering wheel forms the carbureter air control, and another feature of this control is that when pressed it operates an electric horn. The windshield brackets are built into the body. The most important chassis change is the substitution of a disk clutch for the cone formerly used. The motor is a four-cylinder 3 1-2 by 5, block thermo-syphon cooled and fitted with Westinghouse ignition, cranking and lighting system. The wheelbase is 114 inches.

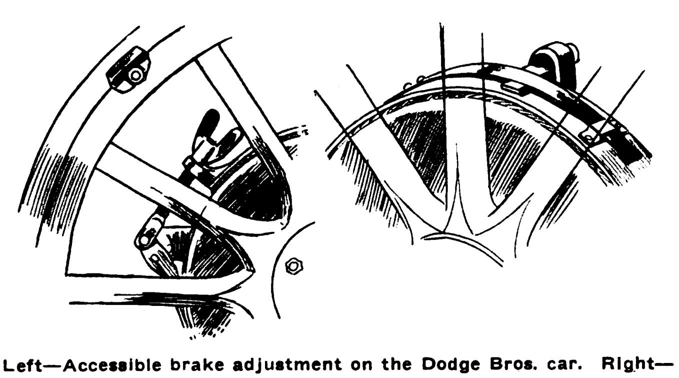
Top side sway has been banished by the new windshield mounting the brackets of which are built into the body. These brackets have attached to them arms which in turn carry conical supporting lugs, which form the connection to the windshield metal frame. The top brackets are attached to eyes on the side arms.—Bartholomew Co., Peoria, Ill.

Grant Adds a Six

A six at $795 is the offering of the Grant company for this season. In addition to this the four-cylinder model has been improved and continued.

The six which will be the leader has a 106-inch wheelbase, standard tread and is equipped with a 2.875 by 4.25 inch block motor. Other specifications are a three-speed gearset, floating rear axle, left drive, center control, cone clutch, cantilever rear spring suspension, unit electric motor generator for lighting and cranking and cowl gasoline tank. The price mentioned is inclusive, but if it is desired a car can be had for $45 less without electric cranking and lighting. In this case acetylene lamps are fitted. The body is a five-passenger touring type with boat lines, having a sheered gunwale. The power plant of the six is a unit and the valves are in the heads of the cylinders. The motor is cooled by the thermo-syphon system and lubricated by a combination splash and pressure system in which the oil is circulated by a gear pump. Ignition is accomplished by means of current taken from the storage battery and distributed by the Atwater-Kent system with automatic advance.

The four has a 2.75 by 4 L-head block power plant with the valves on the left. It is also cooled by the thermo-syphon system and oiled by splash with a vacuum feed. A single ignition system is used in which the current is furnished by a Swiss magneto with hand spark control. The carbureter is a Mayer fed by gravity. The electric lighting and starting system is the Allis-Chalmers. A cone clutch is used in connection with a progressive two-speed gearbox on the rear axle. The axle itself is three-quarter floating and the drive is taken through a torsion tube and radius rod. The wheelbase is 90 inches, the wheels wire and the tires 28 by 3 clinchers. This model is only made up in a roadster body.—Grant Motor Co., Detroit, Mich.



Left—Accessible brake adjustment on the Dodge Bros. car. Right—Light spring to hold brake band off brake drum on the Chevrolet

Great Eagle to Order

The Great Eagle six-cylinder cars are made-to-order propositions, most of the inclosed cars being of large carrying capacity. A ten-passenger limousine is a feature of the line.—United States Carriage Co., Columbus, O.

Haynes Has New Six

There is a new Haynes six with 121-inch wheelbase for three smaller bodies and a 127-inch wheelbase for the seven-passenger body. There is also a larger six and a four which are continued models.

The new six is quite different from other Haynes cars. The electric method of gear shifting used in 1914 is not employed. The vacuum feed for gasoline is used. A motor-driven tire pump has been added and in body work there has been considerable change to conform to the latest dictates of streamline fashion. The radiator has rounded edges and the hood tapers slightly to the cowl. The lines of the body are horizontal from the center of the front door to the rear with no upholstery visible above the top line, but instead the body sides are topped with strips of polished wood. The long straight body lines give a racy appearance, which is assisted by underslinging the springs and lowering the car.

The motor, a block casting 3.5 by 5, is a part of a unit power plant, with the valves inclosed and clean exterior appearace a feature. Hot air intake is fitted to the Rayfield carbureter and the Stewart vacuum tank is mounted on the dash with the gasoline tank carried on the rear between the frame members.

The big six 4.25 by 5.5 with L-head cylinders cast in pairs, has the motor supported at four points and lubricated by a circulating splash system using a plunger pump in the lower part of the crankcase. Ignition is by a Simms high-tension, dual system and starting and lighting are provided by a Leece-Neville system in connection with a Willard battery. The contracting band clutch and three-speed gearset are used in conjunction with a floating axle.

The four, similar in dimensions and detail to the big six, has a 4.25 by 5.5 L-head motor, with cylinders in pairs, and uses the same lubrication, ignition and carburetion system as the larger car. The clutch and running gear are also the same. The wheelbase is 118 inches as compared with 130 inches on the big six.—Haynes Automobile Co., Kokomo, Ind.

Herff-Brooks New Bodies

The Herff-Brooks company is turning out two models, a four and a six, both with new streamline bodies, folding down steering wheel hinged so that the driver may enter or leave the car without wheel interference, Stromberg carbureter, right drive and center control instead of left and center. Bosch ignition instead of magneto and dry cells. Apelco cranking and lighting is new and a one-man top is substituted for the regular type. The five-passenger models now have an extra folding seat for a sixth person, which, when not used is placed in a tool box under the front seat.

Aside from these changes the four has had the wheelbase increased from 116 to 118 inches and the motor bore 3-8 inch to 4 1-2.

The six motor is an L-head with separately cast cylinders 4 by 4 1-2. This method of casting calls for a rather long crankshaft and hence more than the usual number of supports. In this engine seven bearings are used. Power transmission is through an inverted-cone clutch equipped with a brake to a three-speed gearset redesigned slightly to care for the central control.

The four-cylinder car has a larger motor and the cylinders are block cast, L-head design and equipped with same accessories as the six.—Herff-Brooks Corp., Indianapolis, Ind.

Herreshoff Narrow Tread

The Herreshoff of this season is an entirely new product and put out by an entirely different concern than the Herreshoff of last year. Although the Herreshoff Light Car Co., the maker, is an outgrowth of the former Herreshoff Motor Co., the two cars are entirely distinct. The Herreshoff for this season is built only in a roadster form on a 94-inch wheelbase with a 44-inch tread. It has a four-cylinder block power plant with 2.375 by 3.25 cylinders. The valves are on the right side of the cylinder casting and are inclosed by side plates.

Everything about the car corresponds to the practice used in the manufacture of larger cars and the equipment is complete in every respect. Cooling is taken care of by a thermosyphon system without a fan. Lubrication is by combination pressure feed and splash and ignition by the Atwater Kent system with automatic distributer.

Gasoline is fed by gravity from the four-gallon tank located beneath the cowl to a Carter carbureter. A complete Entz-Dyneto starting and lighting system in connection with a Willard 80-ampere-hour battery is part of the standard equipment.

The three-speed gearbox is located amidship and the drive is taken through a semi-floating axle. The wheels are wire, with clincher rims and quarter elliptic springs are used all around.—Herreshoff Light Car Co., Troy, N. Y.

Hudson Stiffens Crankshaft

Hudson has two sixes, the leader designated as model six-40, having a number of refinements principally in motor and chassis and being reduced in price from $1,750 to $1,550, and the larger model six-54, which is but little changed.

The general mechanical layout of the six-40 and the outward appearance are practically the same as last season, although several detail changes have been effected, such as the use of a single casting for the six cylinders, instead of their being cast in groups of three. This makes it possible to eliminate an external intake manifold, the gas distribution from the carbureter being by cored passages in the cylinder casting. Due to finer balance of reciprocating parts and to an increase of 1-8 inch to the crankshaft diameter, the horsepower has been augmented, it ranging from 40 to 47, this attained by the resultant smoother running action.

The dimensions of the motor are of the popular 3 1-2 by 5 size, and L-head construction with gearset in unit is used. In the cooling system a more efficient type of radiator is employed, while automatic spark advance has been added to the hand lever advance. This is an improvement which is made in the combination Delco unit which supplies current for lights, and takes care of cranking as well as ignition.

In the six-40 chassis, the principal refinements are the replacing of a solid tapered driveshaft by a tubular type of uniform cross section throughout; by the use of self-lubricating bushings in the steering connections, brake shafts and steering column tube, making attention to them practically unnecessary; and by the lightening of the weight of the cowl gasoline tank by making the fittings of pressed steel instead of cast iron.

Other chassis features of the six-40 are the Hotchkiss drive through the rear springs, the tapered frame, which gives good body support and the speedometer drive from the propeller shaft. The car has 123-inch wheelbase with left drive and center control.

The six-54 has much the same appearance as the smaller six, though on a somewhat larger scale. The motor is a 4 1-8 by 5 1-4, of L-head type, with cylinders in threes. Delco combination electrical system is also used, while a four-speed gearset with direct on third still features the car. The drive shaft is of the double universal type, but a torsion arm takes drive and torque. The frame tapers as does the six-40, and left drive with center control are provided. The cowl gasoline tank is also used. Wheelbase is 135 inches.

An attractive line of closed bodies is supplied for either chassis.—Hudson Motor Car Co., Detroit, Mich.

Hupmobile Changes Design

An entirely new car is now being marketed by the Hupp Motor Car Co. The design of 1914 has been entirely displaced by it. The new model is a larger and more powerful design embodying among other features new to the Hupp company left drive and center control. The wheelbase is 13 inches longer than the previous one, being 119 inches. The bore is 1-8 inch larger giving a 3.375 by 5.5 power plant with larger water jackets, valves, connecting rods, bearings, ports and manifolds. The Zenith carbureter is still used but instead of the vertical type a horizontal design, 1-4 inch larger is fitted. The carbureter size is now 1.25 inches.

While the Westinghouse outfit is still used it is a single unit instead of a double unit system. The magneto has been dropped and in its place the Atwater Kent distributer substituted. With the fitting of the new distributer many exterior features of the motor have been altered. A new fan bracket with a tension coil spring is an example.

In rearranging the motor the drive of the camshaft has been moved back to accommodate the new position of the carbureter and while the oiling system has not been altered so far as the motor is concerned it is now arranged so that it does not feed to the gearbox, the object being to use a heavier lubricant at this point.

The clutch is the same in principle as in the last model but has been completely reversed, the purpose being to put the thrust drag on the gearbox rather than on the motor when slipping the clutch. The diameter of the clutch remains the same at 13 inches, but the number of plates has been increased by four. There are now 13. Just back of the clutch is a new chassis frame member which acts as stiffener and carries the pedal shaft. The entire rear axle is new and the body larger with streamline form. The spring suspension is now semi-elliptic all around instead of the cross rear spring.—Hupp Motor Car Co., Detroit, Mich.

Imperial Uses Cowl Tank

The Imperials are three in number—two sixes and a four. The four has a 115-inch wheelbase and 3 3-4 by 5 Continental, L-head block motor rated at 22.5 S. A. E. horsepower. Gray & Davis cranking and lighting, thermo-syphon cooling, cowl fuel tank and streamline body with sloping bonnet and rounded-top radiator are other features. The cowl fuel tank is new to Imperial practice. Ignition is by Atwater-Kent Unisparker. The gearset forms a unit with the engine, and drive is through multiple steel-disk clutch and uninclosed driveshaft with two universals. This latter is a departure from preceding Imperial four-cylinder practice, the shafts being heretofore in torsion tubes. The rear axle is floating and 12-inch brake drums are a part of the unit.

In the new six, Imperial has brought out a car of exceedingly trim lines. Mounted on a 130-inch wheelbase, the car is driven by a 3 3-4 by 5 1-4 Continental unit power plant, with cylinders in threes, and valves on the right. Centrifugal pump cooling, North-East cranking and lighting are used. The clutch is a disk type and drive is through a shaft enclosed within a torsion tube. The rear axle is floating, its brake diameter 16 inches and the drive ratio 3 7-8 to 1. The fittings include 36 by 4 1-2 tires, and Stewart vacuum fuel feed from 20-gallon rear tank.

The other six, model 44, carries the same motor and has practically the same drive features. Its wheelbase is 126 inches, and the five-passenger body is somewhat similar to that mounted on the other six chassis. This car also has North-East cranking and lighting, carries complete equipment and uses 36 by 4 1-2 tires.—Imperial Automobile Co., Jackson, Mich.

Inter-State Builds a Four

Inter-State is marketing a four-cylinder chassis with a touring body. This is one of the concerns which has turned its attention to touring bodies alone and makes roadsters only in sufficient quantities to meet orders. This is an entirely new model for this season. It has its 3.5 by 5 cylinders cast in single block and in place of the L-head design used on the six, marketed last year, now has the valve in the head.

Last year's six had 3 by 5 cylinders, but this concern is among those who have pinned their faith to the smaller fours this season. In fact the motor has a number of tendencies toward what is becoming average American practice. The bore and stroke are almost identical with the average of the dimensions of all American cars. Thermo-syphon cooling is used. This is another change from the methods used on the six, as this had pump circulation.

Another change is in the ignition system, which is now single instead of the double type used previously. Lighting and starting is by electricity, but the manufacturer of this has not as yet been announced.

While a disk clutch was used for the six, a cone clutch delivers the power to the gearset in the four. A complete change in the rear construction and transmission system has been made. While in the six a unit power plant was employed, and the gearbox four forward speeds, a cone clutch is used in the four and the three-speed gearbox is incorporated with the rear axle. Instead of the drive being taken through the springs it is now through a torque tube. The rear axle is three-quarter floating whereas in the six it was floating. The wheelbase of the new car is 110 inches and is fitted with 33 by 4 tires. The six had a wheelbase of 132 inches with 36 by 4.5 tires.—Inter-State Automobile Co., Muncie, Ind.

Jackson Drops a Four

The three-model policy which the Jackson company adhered to in 1914 has given way to greater concentration, in that there are now only two models, a four and a six. The new cars cannot be regarded as continuations of any older models, so different are they mechanically.

As compared with the Olympic of 1914, the new car bearing that name has a 2-inch longer wheelbase, 117 inches. Its motor is also larger, being a 4 1-2 by 5 1-4, whereas the old one was 4 1-8 by 4 3-4. The L-head cylinders are in pairs and gearbox is in unit. Instead of having gearshift and control levers on the left, as in the older model, the center position has been adopted, drive being still on the left. Another change is the use of the Stewart vacuum system of fuel feed, replacing a cowl tank type. The reservoir is now at the rear.

The new four has Auto-Lite starting and lighting, the cranking motor being mounted same as last year—vertically at the front of the engine, driving through an enclosed chain and ratchet construction. Final drive is through a propeller shaft of enclosed type to a floating axle, and the distinctive Jackson spring suspension using elliptics all around is still adhered to.

The six has a 3 1-2 by 5 Northway motor. The engine details are principally L-head and block-cast cylinders with upper half of crankcase in unit. Three detachable cylinder heads are used, each covering two cylinders. The gearbox is in unit with the engine. Delco combination, ignition, lighting and cranking is used, and other specifications include cone clutch, open drive shaft fitted with two universals, floating axle. Unlike the four, the gasoline tank is in the cowl and feeds by gravity.—Jackson Automobile Co., Jackson, Mich.

Jeffery Adds Light Six

With last year's four and six practically unaltered, the Jeffery company has added to its line a new $1,650 six, the Chesterfield, which incorporates worm-drive axle, Stewart vacuum fuel feed, Empico speedometer drive, cantilever rear springs, three-plate, dry-disk clutch in place of the cone which the concern has used in past models and a Daimler type of leather universal joint between clutch and four-speed gearbox. The use of such a joint is new in this country but has met with success abroad. The joint is restricted to use on cars with straight line drive or in those where the shaft angularity is only slight.

The use of a three-plate disk clutch is the only change of importance made in the six formerly called model 96. The four still uses the cone clutch.

The new Chesterfield six uses a small high-speed motor, 3 by 5, with cylinders and the top of the crankcase a single casting. The cranking and lighting system is Bijur and consists of generator and cranking motor assisted by a Willard battery. The cranker, mounted on the left of the engine, has a square-end armature shaft upon which is a sliding pinion. This pinion meshes with teeth on the flywheel when the starting pedal is depressed. The lighting generator driven through the timing gears is mounted on the left of the motor with the regulator set on top of the generator housing. The regulator cuts in at between 7 and 8 miles per hour car speed.

Between the motor and the four-speed gearbox is a new three-plate, dry-disk clutch. From the gearset transmission is by spicer-joint shaft to an over-type worm gear driving a floating axle. It has 122-inch wheelbase and 34 by 4 tires.—Thomas B. Jeffery Co., Kenosha, Wis.

Kearns Tread Now Standard

The Kearns Motor Truck Co. remain in the passenger car field with a light four-cylinder car. This model which was brought out late last season has been lengthened from 90 to 105 inches and instead of offering an option of 44 or 56 inches tread, only the standard is now manufactured. To take care of the heavier body and chassis necessitated by the longer wheelbase, the motor has been increased from 2.75 by 4 to 2.875 by 4.5. Unit power plant scheme, however, with three-point suspension is continued.

In general this car might be said to be typical of the light car design which has become popular in the last season. In line with general practice on cars of this size, single magneto ignition is used, thermo-syphon cooling and gravity fuel feed. Head and tail lamps are electric and there are no side lamps. Fuel is fed to the carbureter by gravity from a 7-gallon gasoline tank. The disk clutch transmits the drive through a three-speed sliding gearset to a three-quarter floating rear axle mounted on ball bearings. The brakes are on the rear wheel and steering and control is optional. The wheel being placed on either the left or right side. Either a two- or four-passenger body, both of roadster lines are placed on this chassis.—Kearns Motor Truck Co., Beavertown, Pa.

King Has a V-Eight

An eight-cylinder, V-type, 2 3-4 by 5 motor installed in a chassis which is similar in design to that used for the four-cylinder model features the line of the King Motor Car Co., Detroit, for 1915. The four-cylinder model brought out in July of last year is a much refined car as compared with the previous year's model, though with full electric equipment it is offered for $30 less than the 1914 price, $1,195.

This eight-cylinder engine is the second to be installed as standard equipment in an American car, and it is commendably designed for lightness, compactness and accessibility. All valve tappets are readily reached for adjustment which is accomplished by eliminating nearly everything from the space between the two four-cylinder blocks, the centerlines of which are at 90 degrees to each other. The crankshaft is the same in design as that used in a four-cylinder motor, this being possible due to the coupling of two connecting rods to each throw bearing. One rod has a yoked end which grips the outer ends of the bushing, while a small end rod goes between the two parts of the yoke. The bushing is pinned to the yoke rod with which it oscillates with the shaft as its bearing. The inner rod is free to move on the outer surface of the bushing.

The camshaft is directly above the crankshaft and driven by silent chain. Each cam operates two opposite valves through rocker arms with rollers bearing against the cams. These rockers are pivoted to the crankcase. The crankcase, being common to both sets of cylinders, is not much heavier than that of a four, while reciprocating parts have been made as light as possible so as to allow for moderately high speed operation. A spiral gear drive from the camshaft operates the ignition distributer set at the front end of the space between the cylinder blocks. Cooling is of thermo-syphon type and lubrication by force feed from the oil base to the main crankshaft bearings, and thence through drilled holes in the shaft arms to the rod bearings. The oil thrown from these lubricates the camshaft and other parts. The oil pump is driven by the same silent chain which runs from the crankshaft to the camshaft.

The four-cylinder motor is slightly increased in bore from 3⅞ to 3 15-16 inches, the stroke remaining at 5 inches. The general construction of the engine has not been altered however. It is a block-cast, L-head design.

Both power plants incorporate the gearset in unit and are supported at three points. Ward-Leonard lighting and starting by two units is used with both engines.

The wheelbase of the King chassis, which is much the same for both cars, is 113 inches and the rear spring suspension is of the characteristic cantilever construction which was first used in this country on King cars. The clutch is a multiple disk running in oil. The drive is through an enclosed propeller shaft to a floating rear axle, the housing of which is of pressed steel. Left drive and center control are employed, and tires are 33 by 4.—King Motor Car Co., Detroit, Mich.

Kissel Adopts Block

A new six shown as the 42-six has been added to the line of the Kissel company. Of the two other cars in the line, the 36 four and six 48, the former has been reduced in price from $1,850 to $1,450 but the six-48 price is unchanged at $2,350. Two-door touring bodies are being fitted to all the chassis which in the case of the improved models show some mechanical changes.

The model 36 now has a block-cast 4 1-2 by 5 1-2 motor instead of 4 1-2 by 5 1-4 pair-cast engine. Magneto ignition has been dropped and the combination Westinghouse cranking, lighting and ignition adopted, Stewart vacuum fuel feed is used instead of pressure, the tire size reduced from 35 by 4 to 34 by 4, the gear ratios have been altered and the camshaft drives by helical gears instead of silent chain.

The new six-42 has a 126-inch wheelbase and is fitted with a block-case, L-head 3 5-8 by 5 1-2 motor, cone clutch, three-speed gearset and 35 by 4 1-2 tires.

The unique feature of the Kisselkars is the employment of a two-door single-compartment body as standard. The arrangement is made possible by using individual chairs in the driver's compartment, which permits the use of a single door 26 inches wide, on each side of the body, giving entrance to both front and rear seats. The streamline idea is worked out to a nicety in this body job and an uninterrupted surface obtained from the radiator top to the center of the car. In order to make access to the front seats from the rear easy, an aisle 8 inches wide is placed between the forward chairs. Side lamps are dispensed with. The design of the body is used on the four and five-passenger cars and to those preferring the conventional fore-door type, a five and seven-passenger also are offered.

The six 48 power plant consists of a 4 by 5 1-2 block motor, cone clutch and four-speed gearset with direct on third. Unusually large valves are used and the push rods clamped inside the valve inclosures. Instead of being pressed into the cylinders, the guide and rod can be removed easily without lifting the cylinders. Lubrication is by force feed through a drilled crankshaft, the oil being supplied from a self-contained reservoir and is drained back from the pistons to prevent smoking. This engine is built entirely in the Kissel shops.

A feature of the clutch is that it may be adjusted without disturbing any other part.

Centralization of all electric wires on a control panel fastened to the front of the dash is another decided feature and through this arrangement the wiring may be repaired or inspected without disturbing parts foreign to the system. The system makes body removal possible without cutting a wire.

The four-cylinder Kisselkar, the principal data of which were given previously, has a 121 inch wheelbase and is fitted with the two-door bodies described. The clutch is a cone and the gearset, a three-speed selective, the power plant being lighter than that of the model 40 of last season.—Kissel Motor Car Co., Hartford, Wis.

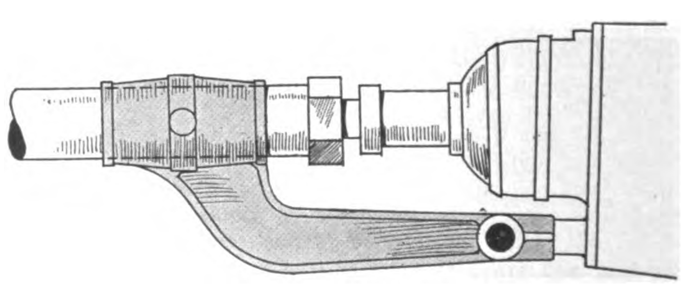
Kline Changes Pivot Point

Two sixes mounted on chassis which are the same in every detail with the exception of the wheelbase will make up the Kline line. These chassis are known respectively as 6-42 and 6-42-A. On the former there are mounted a touring, toy tonneau and roadsted bodies, and on the latter a seven-passenger touring and a seven-passenger limousine. The wheelbases are respectively 123 and 127 inches.

The new six motor is an L-head. The three-point suspension scheme heretofore employed by the Kline company has been changed. The pivot point was formerly at the flywheel but has now been changed to the front on account of the change to the unit power plant. The radiator suspension has also been changed from the main side members to studs placed in the bottom of the radiator. This was done to relieve the strain due to the twisting of the side members.

A four-speed gearset was formerly used but now a three-speed takes its place. The reason advanced for this is that the new motor is more flexible and more powerful and the direct drive is quieter than the over-geared drive.

The electric starting motor has been changed to the left side of the engine and an enclosed Bendix gear fitted. The lighting generator is now on the right side and is driven by the pump shaft at 1.5 crankshaft speed instead of 3 to 1. The Stewart-Warner vacuum feed has replaced gravity feed for



King uses a bracket shaft support which allows for flexure in the cantilever rear springs the gasoline and in body work a streamline design of rounded radiator and hood is another innovation. The entire electric equipment is taken care of by Westinghouse, in conjunction with a Willard battery. The cars on the 127-inch chassis have 35 by 4.5 tires and on the 123-inch chassis 34 by 4.—Kline Motor Car Corp., Richmond, Va.

Krit Uses Bigger Motor

Along with reductions in price, Krit models have larger and more roomy bodies, a more powerful motor and better equipment. All body types are fitted to the one standard chassis of 108-inch wheelbase. The price of the roadster and touring car models corresponding to those of last season is $995 as compared with the old figure of $1,050, this being with North East electrical equipment, one-man top, non-skid tires and additional instrument board units. A cabriolet has been added. In addition, another model with lower-priced equipment is offered on the same chassis for $850.

While all bodies are streamline in design, a new feature on the higher-priced models only is the doing away with all moldings along the top edges, the metal of the sides rounding over the top edges in a smooth curve.

The Krit motor is an L-head block type, 3 3-4 by 4 and about 25 per cent. has been added to its power by increasing the valve diameter from 1 1-4 to 1 3-8 and by lightening the reciprocating parts and by redesigning the cams for wider valve opening and closer tappet adjustment. A new oiling system combines the flywheel pump system (heretofore used) with pump circulation, making it more positive and efficient.

Three chassis changes are of special note. First is the shifting to center from left control; second is the adoption of fore-and-aft steering mechanism to replace the cross type, this relieving the frame of the steering side thrust and therefore making steering easier; and third is the center frame cross member which now houses the brake cross rods and levers, relieving them of twisting strains.

In either roadster or touring form, the special sells for $1,070 with such extra equipment as leather faced seat covers, five wire wheels, and option of color. Still another model is that which sells for $850. This has less of the *de luxe* about its equipment and appearance though from the standpoint of service it is equal to any of the other models. It has Disco electric equipment, and all necessary features for service, but in order to bring the price down, such things as crowned fenders, one-man top, gasoline gauge and so on, which are fitted to the other models, are not included.

The gearbox is in unit with the engine, the propeller shaft is enclosed in a torsion tube, and the axle is semi-floating.—Krit Motor Car Co., Detroit, Mich.

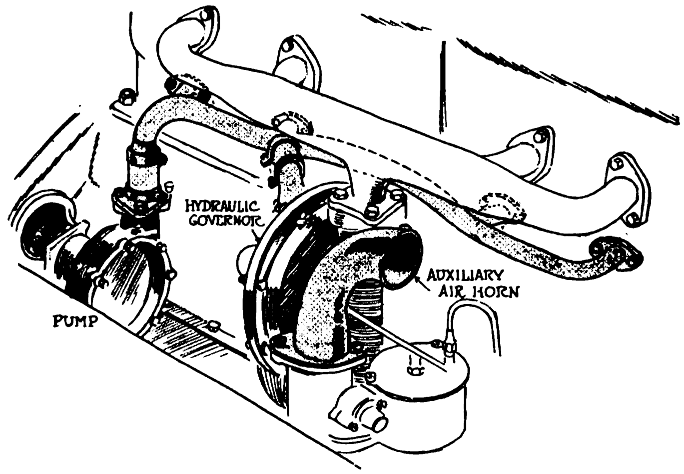
Lambert Alters Jackshaft

Two four-cylinder chassis, one with a 117-inch wheelbase and the other with 112, equipped with either Continental or Rutenber motors, are being continued by the Buckeye company, with a number of changes. These cars are similar in design and while retaining the friction drive which the Lambert has used for many years, the suspension of the jackshaft has been changed slightly so as to make a more accessible construction.

Bodies are entirely new, being of the streamline type with higher sides than formerly and a much wider rear seat. Attention has been paid to the upholstery to obtain more comfortable riding. Instead of using dash lights as heretofore, a small lamp is incorporated in the headlights.

Battery ignition, using the accumulator of the lighting system and a distributer, supplants a magneto. The entire electrical system still is of Briggs make and shows no important changes in the cranking and lighting units.

The cowl gasoline tank has been made larger and the filler neck placed inside the cowl instead of on top outside. Other changes in Lambert cars include the fitting of a ball on the



Packard hydraulic governor for keeping the speed of the motor constant. It is operated by a diaphragm

shifter lever to make speed changes easier and the adoption of a steering post, which, in the course of construction can be varied in length to suit the requirements of the purchaser. The radiator has been improved by giving it a more shapely appearance to conform with the lines of the rest of the car.

The large Lambert chassis is fitted with either Continental or Rutenberg motor, 4 1-8 by 5 1-4 and sells for $1,565 with roadster or touring body. The drive is by friction set and single silent chain to a semi-floating type rear axle.

The 112-inch wheelbase model is fitted with optional motor type as mentioned, but the size is 3 3-4 by 4 and the price $1,200 in five-passenger form.—Buckeye Mfg. Co., Anderson, Ind.

Lexington Has New Six

Three Lexington models are marketed for this season; the leader is a new light six known as the Thoroughbred. In addition there is a larger six and a four.

With the exception of the motor the design of the new six is similar to that of the four. The engine is an L-head block 3.5 by 5 fitted with the Moore multiple exhaust system as are the other motors used in Lexington cars. In this system the exhaust manifold is cast so that the exhaust from each cylinder has an independent passage giving a gain in power through the elimination of the entrance of dead gases into the cylinders. Westinghouse cranking, lighting and ignition is used on this model. Its wheelbase is 128 inches and the transmission system consists of a disk clutch, three-speed gearset having the gearbox bolted to the crankcase and a three-quarter floating rear axle with a ratio of 41. Cantilever springs are used.

The four-cylinder is now equipped with a Teetor T-head power plant whose dimensions are 3.875 by 5.375. Last season the four had an I-head motor with 4 by 5 cylinders. Cantilever rear springs supplant the three-quarter elliptic and another change has been made in the introduction of the Westinghouse cranking, lighting and ignition apparatus. In conjunction with the introduction of the Stewart vacuum gasoline feed the gasoline tank has been moved from under the front seat to the rear of the chassis. Improvements in the form of body work and equipment are notably in the adoption of streamlines and the fitting of a one-person top and a power tire pump.

The large six-cylinder model has not received many mechanical changes as compared to the four. In common with the latter, however, the gasoline feed is now by the Stewart vacuum system and the tank is at the rear instead of under the seat. A power tire pump has also been added to this model and the body lines have been improved so that the hood now slopes from the radiator to the cowl and the instruments are now on a cowl board. Otherwise the six remains the same as for last season.—The Lexington-Howard Co., Connersville, Ind.

Lewis Smacks of Foreign Design

The Lewis six shows no radical changes, but alterations have been made in the adoption of the Stewart vacuum gasoline feed and the Remy electric cranker. The radiator has been rounded slightly.

This car sells at $1,600. The motor shows marked tendencies toward foreign design. Its dimensions are 3 1-2 by 6 and the crankcase and cylinders are cast as a unit. Two other units form the principle motor parts, the cylinder head which is bolted on and the crankcase cover plate. The assembled job gives a decidedly neat appearance, clean, accessible and shows forethought in the positioning of the fittings. The magneto is set transversely on the left in front of the breaker box and distributer facing the outside so that adjustments can be made easily. The carbureter is rather high and about clears the frame. It feeds from a short straight manifold to a passage in the cylinder casting and across the motor to the valves on the opposite side. On the same side is the vacuum feed gasoline tank.

In the motor lubrication combination splash and force feed is employed and not only is the motor properly supplied but the reservoir takes care of the clutch and gearset as well, replenishment being by a flywheel which acts in the capacity of a pump. The lubrication has been carried a step farther and the entire valve mechanism including springs, guides, etc., is housed within the crankcase walls so as to receive proper oil supply by splash, so reducing wear on these parts considerably.

The clutch is a running in oil disk, the gearset a three-speed selective.

The wheelbase is 135 inches and the tires are 36 by 4.—L. P. C. Motor Co., Racine, Wis.

Locomobile Left Drive Only

Two sixes comprise the Locomobile line. They are continuations of the 38 L-D and the 48 L-D of last season with refinements which are principally found in the body and equipment. The two right drive cars built last season have been discontinued, leaving only left drive cars for the 1915 season.

The adoption of the single wiring Westinghouse Electric Light and Starting system with a special push-button control switch designed by the Locomobile engineers is the chief refinement. With this control starting has been reduced to the pressing of a button, the shifting of the starting gear being accomplished electrically through a solenoid instead of manually. All the electrical push-buttons are now placed in a vertical row in the instrument board and the starter button being at the bottom may be operated by the foot. Other refinements include the use of drop forging for many of the small parts such as windshield brackets, bonnet clips, throttle levers, etc. The top is provided with a lining concealing the bows, and in the interior work the decorative scheme has been considerably improved. The fenders are more heavily crowned and are made in one piece, the brakes are 2 inches larger in diameter and the tread has been widened to the standard 56 instead of 54.5.

The two motors for the 38 and 48 are similar in design and do not depart from Locomobile practice of the last two years except that when the company changed to left drive last season the alterations necessary in putting the steering column on the other side of the motor had to be made. Both motors have T-head cylinders cast in pairs. The sizes are respectively 4.25 by 5 and 4.5 by 5.5. The makers claim horsepower output of 63 and 82 at 1,800 r.p.m. In the body work luxury has been the keynote of design and the roadster is featured by a rear deck with a folding compartment containing extra seats for two passengers.—Locomobile Co. of America, Bridgeport, Conn.

Lyons-Knight Uses Worm Drive

No changes of importance have been made in the four-cylinder Lyons-Knight model K.

Aside from its sleeve-valve engine the feature of this car is the worm-drive axle incorporating the gearset, the only American car on the market using this combination. The worm is mounted above the worm wheel and gives an axle clearance of 10 inches.

The motor, 4.5 by 5.5 with pair-cast cylinders, uses aluminum for the cylinder head covers and chain case. The covering for the cylinder heads is designed to keep out dirt and moisture and protect the spark plugs, this being exclusive with the Lyons motor. Force feed lubrication is used for the sleeves, all bearings and the pistons. A plunger pump, controlled by one of the eccentric rods, takes oil from a reservoir in a sump in the crankcase, and forces it under pressure to the crankshaft and eccentric shaft bearings, the eccentric rod bearings and then through a duct in the crankshaft center to the connecting-rods. These rods are hollow and the oil is forced upward in them to the top rod bearings, thence to hollow piston pins to the piston exterior and through holes in the sleeves to the cylinder walls. The oil pressure is in proportion to motor speed.

A single-unit North East cranking and lighting device drives by silent chain from the front end of the crankshaft. A three-plate dry-disk clutch and three-speed selective gearset take the motor drive.—Lyons Atlas Co., Indianapolis, Ind.

Marmon Refines Small Six

As heretofore, Marmon has two sixes, the larger continued without change, and the smaller model 41 a refined edition of the former small six. The most radical change is in the equipment, namely the full Bosch outfit, including, magneto, starter and generator all in separate units and in addition all the switches, wiring, lamps, bulbs, etc. Marmon was the first company to adopt the system.

The smaller model is a more attractive job than its predecessor, in that the body lines have been considerably beautified, with the sides higher, together with a sloping hood and rounded radiator. The fenders have a different camber and the luggage carrier and battery box have been removed from the running boards, leaving these free and clear.

A few motor changes have been made, due to the new lighting, starting and ignition system. In order to avoid running the magneto shaft through the pumps the latter has been moved forward. Pistons are longer with three rings above the wrist pin. The upper two are concentric packing rings and the lower a concentric oil ring with nine .125-inch holes drilled around the circumference at an angle of 45 degrees to the axis of the cylinder.

The starting motor engages with a gear connected with the flywheel, whereas in previous models the starter insulation was by chain drive in a separate housing in the rear of the motor. A new design of cone clutch faced with thermoid is used. The Stromberg carbureter, Silvertown cord tires, one-man top, and larger brake cams are features. The 4.25 by 5.5, L-head power plant with cylinders cast in threes is continued. On this chassis there is a five-passenger body at $3,250. Roadster and speedster at the same price, and in the more expensive bodies there is a seven-passenger touring design at $3,350.—Nordyke & Marmon Co., Indianapolis, Ind.

Maxwell Revises Exterior

The 1915 Maxwell 25, the only chassis model which the Maxwell Co. is making, is much altered in outward appearance from its predecessor, largely due to the sloping body and hood, and the crowned fenders. With these new clothes and several mechanical changes, there is a uniform reduction of $55 throughout the line of body types. However, if starting and lighting by electricity are required instead of the gas and oil lighting furnished at the above prices, $55 must be added to the price of any model. Thus, the price of the electrified car is the same as that of last season's car without such advantages.

Besides the new form of bodies, the gasoline tank has been shifted from under the seat to the cowl position, while another important change is the replacement of the semi-elliptic rear springs, which are connected to spring horns at their rear ends, by three-quarter rear springs having scroll ends. On the motor, the carbureter has been shifted from the left of the engine to the right to make room for the electrical units when supplied. A new radiator construction is also used in which the shell is separate from the core, and any jar which the former receives is not transferred to the delicate core, thus making less the possibility of springing leaks.

The Maxwell chassis is of 103-inch wheelbase and has a 3 5-8 by 4 1-2 block, L-head motor, with the three-speed gearbox in unit. The drive features include cone clutch, enclosed propeller shaft and three-quarter floating rear axle. Left drive and center control are used, and the tire equipment is 30 by 3 1-2 all around.

The body is entirely smooth, and door latches and hinges are concealed. One other improvement is the addition of an instrument board which carries the usual array of control devices as well as the filler cap for the gasoline tank.—Maxwell Motor Co., Detroit, Mich.

McFarlan Adopts Cone Clutch

Five changes of importance show in the McFarlan the six. These changes are: The adoption of a cone instead of a disk clutch, Stewart vacuum gasoline feed in place of pressure, increase in the wheelbase 4 inches to 132, option of electric in place of a pneumatic cranking system, and the fitting of a new body. The single chassis is fitted with either a 4 by 6 or 4 1-3 by 6 motor.

The motor, a T-head block design, is regularly fitted with Westinghouse lighting and ignition system, but the Westinghouse cranking unit is optional, as stated. In the generating system the current output increases when the load on the battery increases, which is effective in keeping the battery charged at all times. There is not an exposed wire, flexible conduits being used for housing them and the conductors.

The new clutch is a 16-inch cone, with twelve flat adjustable springs under the leather. The entire unit is comparatively light, peripheral weight reduction resulting in the stoppage of clutch spinning and hence making gearshifting easier. The gearbox still has three speeds and is unit with the floating axle.

The body is lower and the lines have been improved upon. There is a small cowl over the back of the front seat which serves not only to show fashion advancement, but also is practical for the carrying of parcels, gloves, hand bags, etc. The upholstery does not extend over the body edge at any point.—McFarlan Motors Co., Connersville, Ind.

McIntyre Imp Drops Air Cooling

While the McIntyre company is manufacturing three models, one of them, the four-cylinder model 25, is taking almost the entire energy of the plant. This model, in five-passenger form, is the best appearing job which has up to this time been marketed by the company. The others are model 6-40 Hoosier, and the Imp the second, the reconstructed cyclecar, which, however, shows little of the original car's design. The 6-40 Hoosier was called the 6-40 Limited in 1914 and mechanically there has been but one important change made, that of transferring the steering post from right to left side. The price has been reduced from $1,685 to $1,275, and a one-man top added. The Imp model now has a four-cylinder water-cooled motor and a side-by-side body instead of two-cylinder air-cooled engine and tandem seating.

On the new model 25 a slope from windshield to a V-shaped radiator which is longer than is usually seen is used. The wheelbase is 106 inches.

A Golden, Belknap and Swartz motor, 3 3-4 by 4 1-4 with L-head, block-cast cylinders is used. Cooling is by the thermo-syphon system and oiling by force feed and splash in which a plunger pump takes oil from the crankcase and forces it through a dash sight feed from whence it travels to the crankshaft bearings, overflowing and dropping again to the reservoir. The clutch is a three-plate running-in-oil type and drives by shaft to a three-speed gearbox. Rear spring suspension is by cantilevers.—W. H. McIntyre Co., Auburn, Ind.

Meteor Has Four and Six

Two models, a four and a six, make up the Meteor line. Both these models with the exception of the power plants and wheelbases are constructed along the same lines. Both are provided with L-head power plants with the cylinders cast in pairs and valves on the left side. The dimensions of the four are 4 by 5 and of the six, 3.75 by 5, the six, although of smaller dimensions, having a higher power rating than the four, the actual figures, being 25.6 and 33.6 by the S. A. E. formula. The piston displacements of these two models are respectively 251.3 and 331.4 inches. The wheelbases are respectively 114 and 126 inches.

Pump water circulation is used in both these cars and lubrication is by a combined pressure and splash feed in which the oil is carried from the reservoir in the crankcase by direct leads to each of the main bearings. The oil which flows from these bearings supplies the splash troughs which are located beneath each connecting rod throw.

Electrical equipment for both cars is furnished by the Splitdorf-Apple apparatus for starting and lighting and the Atwater Kent system for ignition. The battery is the sole scurce of ignition current and the control of the spark advance is either hand or automatic as suits the driver. That is, should the spark lever not be used the automatic advance would take care of the spark position but if desired a change in advance can be made by using the hand lever.

Both models use disk clutches and three speed gearboxes, both clutches and gearboxes being combined with the motor to form a unit power plant. The final drive is by bevel gear, torque and drive being taken through the springs. Both cars have the same reduction gears in the rear axles, the final ratio being 3.7 to 1. The tires on the four are 34 by 4, and on the six, 35 by 4. The wheels are wood. The steering wheels are located on the left with the control levers in the center. The four is fitted with only one type of body, this being a five-passenger touring at $1,075.—Meteor Motor Car Co., Shelbyville, Ind.

Metz Adds Larger Model

The introduction of an entirely new chassis upon which a touring body is mounted is a radical departure from previous Metz practice which has confined itself thus far to roadster and raceabout constructions. While the new chassis is larger throughout than the one on which the roadster continued to be mounted the principles of construction are the same. The motor has .125-inch more bore than that used on the roadster but the stroke is the same, the dimensions being 3.875 by 4.

Other than the dimensions of the motor and the necessity for making the parts larger throughout a description of the smaller Metz will serve for the larger. The tires on the touring car, however, are 32 by 3.5 inches, the wheels are wire and the wheelbase 105 inches. The new car is fitted with Bosch magneto and a Gray & Davis 6-volt electric starting and lighting system. Left drive and center control are used. The friction drive which has characterized Metz cars in the past remains the same.

Improving the appearance and bettering the equipment has been the extent of the changes made in the Metz roadster. As far as mechanical changes are concerned there are none except those necessitated by a 6-inch increase in the wheelbase and the fitting of the gasoline tank in the cowl.

The L-head 3.75 by 4-inch motor is cast in block with enclosed valves. The crankshaft and camshaft are steel forgings ground to a finish fit and carried in white metal bearings. The motor is lubricated by constant-level splash with pump circulation. Cooling is by thermo-syphon and ignition by a Single Bosch high-tension system.

There is no clutch on the Metz car, speed changes being effected by sliding the friction wheel along the face of its driving disk. When the drive is arranged to take its lowest reduction, or, in other words, on direct a ratio of 3 to 1 is provided. The frame is of pressed steel and the springs are full elliptic. The tires are 30 by 3 inches.—The Metz Co., Waltham, Mass.

Mitchell Adds Two Models

Two new cars, a four and a six of design practically the same throughout, are featured by the Mitchell-Lewis company for 1915. The four-cylinder model which sold for $1,585 has been discontinued.

The motor size of the new four and six is the same and the design of the other chassis parts also, hence a description of the four will do for the six.

The new four and six are the only 1915 Mitchells with a motor using L-head cylinders and these are 4 by 5 1-2, cast in pairs. Light reciprocating parts and balance of parts has been given special attention so as to reduce vibration. The oiling system makes use of a plunger pump which forces oil from a reservoir in the crankcase to troughs under the connecting rods, to the timing gears, to the silent chain at the front of the engine and to the dash sight feed which has two outlets, one leading to the clutch bearing through a flexible tube and the other to the rear crankshaft bearing. A breather arrangement from the crankcase to the valve chambers offers a means of valve mechanism lubrication by oil vapor from within.

Simplicity is seen in the fan and water pump assembly. A centrifugal pump operating at unusually high speed is mounted upon the front end of the fan shaft where it is accessible, close to the radiator, driven without extra mechanism and should the water within become frozen, and injure the pump, the outlets are large enough to cool the engine by the syphonic system.

The exhaust manifold instead of discharging at the rear does so at the front, which lessens the heat under the driver's seat and provides a cooling means for the exhaust pipe, it being in range of the cooling fan draught.

The drive from this motor is by a cone clutch of new design using a light, stamped-steel member with three steel coil springs under the leather to make engagement smooth. A three-speed gearset is bolted to the front end of a torque tube which incloses the drive shaft. Bevel final drive in a floating axle is used as in past Mitchell practice.

The wheelbase of the car is 116 inches, tires 34 by 4 and the equipment includes an Apelco cranking and lighting system of the unit type, the motor-generator being driven by silent chain and geared 2.6 to 1 with the motor. Control is such that at 8 miles per hour the generator is delivering 6 amperes to the storage battery which is located on the running board.

Insofar as design is concerned the special six and de luxe six, the three continued cars, are practically the same. The principal dimension differences lie in the wheelbase. The special four is 120 inches from wheel to wheel, the special six 132 and the de Luxe six, 144. The motors in all are 4 1-4 by 7, T-head jobs cast in pairs and using Remy ignition and Rayfield carbureter. The drive in all is like that of the new four which adheres to Mitchell past design.—Mitchell-Lewis Motor Co., Racine, Wis.

Moline-Knight Four Speeds

The Moline-Knight made in one model, sells at $2,500 or $100 more than last season. The increase is due to many changes, chief among which is the adoption of a four-speed gearset. This gearset is used only on the open cars and has been separated from the motor, thus abandoning unit power plant construction and using four- instead of three-point motor suspension. The separation of the units was necessary because of the new gearset and brought with it the desired result of eliminating the gear noises magnified by the sounding-board characteristics of the large aluminum housing previously used. The new gearset has made it necessary also to use a sub-frame with the result that gear shift lever and hand brake lever are nearer the front seat and more accessible to the driver.

The next important place of reconstruction is in the rear axle which now employs spiral-bevel gears. A third change is in the motor where the exhaust manifold, formerly waterjacketed and cast with the cylinders, now is bolted on and not waterjacketed, thus effecting better cooling of the cylinders themselves. Other slight changes are the substitution of a screw-and-nut steering post for the worm-and-sector; the fitting of a single-cylinder motor-driven tire pump instead of the two-cylinder pump and the use of Whitney chains for driving the motor shafting.

The Moline-Knight engine, 4 by 6, is the first block cast Knight to be announced in America and one of two offered this year. Thermo-syphon cooling is another departure from conventional Knight practice and this is the only motor so cooled. The water travels from the radiator through a two-arm manifold, the arms attaching to the lowermost portion of the cylinder casting. The water circulates the entire length of the cylinder barrel through the intake manifold around the cylinder head and tops of the sleeves and goes so far as to cool the portion around the spark plugs.

The oiling system through a gear pump forces oil, at pressures up to 40 pounds, to every part requiring lubrication. The first passage to receive oil from the pump is a duct which extends the entire length of the crankshaft bearing plate and is tapped at three places where leads go to the main bearings. At the main bearing wrist holes are drilled in the crankshaft, the holes communicating with the connecting rod bearings. The rod bearing hole registers once each revolution with a hole in the upper portion of the rod bearing. This hole communicates with the hollow rod which receives oil to feed to the wristpin. An automatic governor connected with the throttle regulates the oil pressure in proportion to the speed.

The motor uses Bosch duplex ignition, Schebler carbureter and the drive from it is by cone clutch and new gearbox to a floating axle. Cranking and lighting is by the Wagner 12-volt, two-unit system.—Moline Automobile Co., East Moline, Ill.

Monarch Makes a Six

Monarch is offering a six this season. This machine, with 3 1-2 by 5 Continental motor and wheelbase of 125 inches, is the only model now made by the concern, which last year marketed two fours and a six.

The block type, L-head engine has the gearset in unit, and the whole assembly is three-point suspended. Cooling is by centrifugal pump, and ignition is by Atwater Kent with lighting and cranking by Ward Leonard equipment. The cranking function is worked out through application of the turning effort to the flywheel through the Bendix drive mechanism.

Other design features include left drive and center control, Hartford cone clutch having springs under the leather, 13-gallon cowl gasoline tank, Salisbury three-quarter floating axle, wood wheels carrying 33 by 4 tires on demountable rims and elliptic rear springs.

The body has no exposed door hinges or latches, and running boards are also clear. The front seat is divided, and Turkish upholstery makes comfortable riding. The price of $1,250 is with five-passenger body, although it is plenty roomy for two extra seats, these being obtainable to fit the car at an extra cost of $25.—Monarch Motor Car Co., Detroit, Mich.

Monroe Has Block I-Head

A new roadster has been announced by the Monroe company which, while a new concern to the industry, is closely related to the Chevrolet company through the possession of common stockholders. The car is in the low-priced class, selling for $460. It has a block motor with valve-in-head and in general lines resembles very much the Little car formerly produced by the Chevrolet company. The 3 by 3.75 power plant delivers the power through a 10.5-inch clutch to a three-speed gearset.

In spite of the low price of the car it is thoroughly up-to-date with its electric equipment, being fitted with electric lighting and for $35 extra with electric starting. The generator is on the right side of the motor and is at the forward end, being driven from the timing gears. When the starting motor is fitted it is on the same side of the engine and engages with the flywheel by means of spur teeth. The engagement of the driving pinion of the starting motor is controlled by a Bendix gear.

Thermo-syphon cooling is used and the radiator is supplied with an auxiliary tank at the top. A belt-driven fan also aids in the cooling.

A combination splash and pressure system takes care of lubrication. The pump delivers the oil to the connecting rods, bearings and timing gears, and the cylinders receive their lubrication through the splash.

The gears used in the gearbox are nickel steel and they are carried on ball bearings throughout. The shifting lever is mounted directly at the rear of the gearbox and provides a direct control of the gearbox without intermediate levers. The rear axle is semi-floating and torque is taken through a tube connected to the rear end of the gearbox by a forked yoke. Steering is by a worm and gear with spark and throttle lever mounted under the wheel. The control instruments such as the ignition switch, dimming switch and ammeter are on the cowl board.—Monroe Motor Co., Flint, Mich.

Moon with Hotchkiss Drive

Two sixes have been added to the Moon line. The new cars show evidence of past Moon practice and the departures are in the nature of weight-reduction, the obtaining of better riding, new bodies, a new type of disk clutch, Hotchkiss drive, Stewart vacuum fuel feed and a new rounded radiator.

The model 6-50 has a 130-inch wheelbase instead of 129-inch, the doors have been widened 1 inch to 22 inches and the upholstery is deeper. There is more legroom. In reconstructing the clutch the wear on the plates has been reduced, due to a new manner of holding them. In the rear axle, a crucible steel housing takes the place of malleable iron, which reduces the weight about 100 pounds. Two inches greater diameter brings the drums to 16 inches, and a new brake-equalizing system has been installed. The Delco distributer is operated by silent chains instead of gears, and the equipment has been broadened so as to include Stewart vacuum fuel feed and Klaxon horn. The price still is $2,250.

The two new cars are similar in construction and general appearance and should be admired chiefly for the body design.

The chassis features of both the 6-40 and the 4-38 are the same but the former has slightly heavier parts. The motor dimensions of the four are 3 3-4 by 5 and the six 3 1-2 by 5. An improved one-wire Delco system is used and Stewart vacuum feed added. As a unit with the motor is a dry-disk clutch and a three-speed gearset, products of the Warner Gear Co.

Propulsion is through the springs constituting the Hotchkiss drive which eliminates the torque rod and makes the springs take most of the driving strains. A new braking system is used and the number of brake-system parts is reduced from 50 to 22. In the new system a more direct action from pedal to bands is obtained with a smaller equalizing beam at the rear almost above the axle housing. Last season a long beam was used in the center of the chassis. Both cars have 122-inch wheelbase and 34 by 4 tires, underslung rear springs and dimmers in the headlights.

The 6-50 has a 3 3-4 by 5 1-4 motor, new disk clutch, four-speed gearset, floating axle and new braking system.—Moon Motor Car Co., St. Louis, Mo.

National Stiffens Crankcase

The National line is the same six and four as in 1914. Mechanically the cars are practically unchanged except that in the six several refinements have been made. The chief change is the fitting of an entirely new electrical outfit comprising the Eisemann magneto which serves as the sole source of ignition current, and the Westinghouse starting and lighting outfit which replaces that formerly used. In refining the motor, 25 per cent. has been cut off the weight of the reciprocating parts. The crankcase is heavier and more rigid and an improved type of oil screen is fitted. In the gearbox the travel of the sliding pinion is increased .25 inch. Silico-manganese steel replaces carbon steel in the springs. Larger wheel bearings are used. Wheelbase is 134 inches.

The power plant of the six is a 3.75 by 5.5, L-head, block design with waterjacketed intake manifold and with the valve mechanism inclosed. The newest Rayfield carbureter has been fitted in connection wtih a pressure feed gasoline system. The four, a 4.875 by 6, T-head design has its cylinders in pairs.

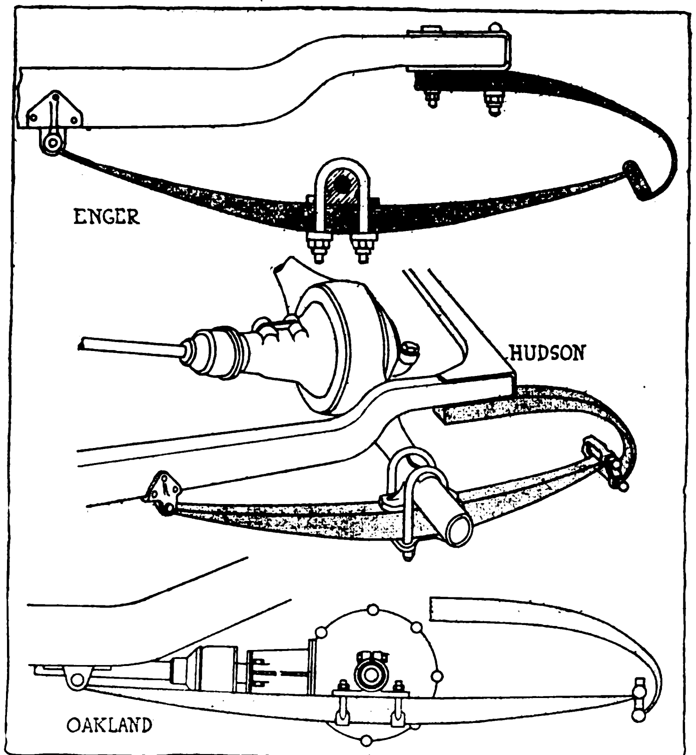
In body work the National company is featuring a four-passenger boat design with four individual seats mounted on tracks so that they can be placed about the body in nearly any desired position. There is a fifth additional seat which folds into the rear of the body. It is invisible except when in use. The entire body follows boat practice with a curved gunwale line and moulded fore and aft curvature. The other standard bodies have been brought thoroughly up to date and follow streamline practice. The six sells for $2,375 and the price of the four is $2,750.—National Motor Vehicle Co., Indianapolis, Ind.

Norwalk Adopts Monoblock

Norwalk has dropped one model and added another for this season. Last year two sixes were marketed, known as C and D. The model which has been dropped is the D, which leaves the larger six continued and the new model F is a distinct departure from previous Norwalk practice. It is also a six but instead of having the cylinders cast in threes, it has a mono-block construction. In all other respects the chassis itself is practically the same as the model D but in the matter of outfitting, the single wire system is used instead of the double wire; double bulb headlights are used instead of side lights and control is by hand instead of electric.

The body styles marketed for this season are for the model C, a six-passenger touring, an open and a closed limousine. For model F, there is a two-passenger roadster, six-passenger touring, two-passenger coupé, four-passenger sedan and six-passenger limousine.

The model F which will be the leader for this season has



Upper—Rear spring suspension on the Enger. Middle—Rear construction employed on the Hudson, showing springs slung under the rear axle. Lower—Oakland rear construction, showing method of carrying springs under axle

its six 3.5 by 5.125 L-head cylinders cast in a single block with the crankcase continued back to include the clutch and four-speed gearbox forming a unit power plant. This plant is suspended at three points. The valves are all on the left side and are driven from a unit camshaft which is operated by helical gears. The intake manifold is a unit with the cylinder casting and the exhaust separate.

Cooling is effected by a centrifugal pump through a cellular radiator. Lubrication is taken care of by a splash pressure system in which a gear pump takes the oil from a crankcase, sends it to the main bearings under pressure and from there it flows to the splash troughs beneath the connecting-rods. Ignition is accomplished by a single high-tension system in which the battery is the current source and an Atwater Kent distributer and coil form the balance of the system. Gasoline feed is by the new vacuum system, Gray & Davis starting and lighting are used and the transmission system is comprised of a disk clutch selective gearset and semi-floating rear axle which has a double gear reduction. The drive is taken through the springs. The wheelbase is 131 inches and the tires 37 by 4.—Norwalk Motor Car Co., Martinsburg, W. Va.

Oakland Multiple Piston Rings

With a very attractive design of bodies that are a modification of the boat body lines which have appeared in Europe, the Oaklands of 1915 are mounted on either a four- or a six-cylinder chassis. The four, model 37, is a much-altered continuation of model 35 of last season, and the six-49 is the successor of the 1914 model 48. The six is reduced $100 to $1,685. Although the last named has not come in for much mechanical change, the model 37 is practically a new job throughout its mechanical features.

The motor operates at speeds up to 2,500 or 2,600 r.p.m., and is a 3 1-2 by 5 block type with detachable heads and gearbox in unit, and suspended at three points in the frame. Pistons have been crowned to make them stronger, multiple thin steel piston rings have been fitted and the throttle axis of the carbureter has been arranged parallel to the centerline of the motor so as to make less restriction to gas passage and valve diameter and lift have been increased. These things have contributed to the increased power of the engine.

Delco ignition, lighting and cranking are employed, as is the Stewart vacuum fuel feed with tank at the rear. A unique feature of the four chassis is the elimination of bearings on emergency brake lever, gearshifting lever, brake rods, clutch shifter, clutch link, and so on. This is done by the use of springs and wedges, the former holding trunnions or other projections on the parts down against fixed supports and allowing them to move back and forth due to the compressibility of the spring. Thus they are prevented from vibrating, do not require oiling, and the like. Similar wedges connect brake rods to their levers, these allowing the necessary movement without bearings.

A tubular propeller shaft replaces a solid one; the three-quarter floating axle has given way to a floating construction; and the frame has been re-shaped so as to follow the body line and thus give substantial support. Underslung springs at the rear help the low-hung appearance. The wheelbase is 112 inches and tires are 33 by 4 on demountable rims.

The six-49 is fitted with either roadster or seven-passenger touring body. The motor has the same improvements as the four, and is a 3 1-2 by 5, with cylinders in block and heads detachable. Equipped with a three-speed gearset, cone clutch, uninclosed drive shaft, underslung front and rear springs, Delco combination electrical unit and Stewart vacuum fuel feed.—Oakland Motor Car Co., Pontiac, Mich.

Oldsmobile Advances Front Axle

With very little change of any kind, the Oldsmobile four and six are combined, the former having made its appearance early last year as the consort of the well-known big six. This four-cylinder car, however, has been reduced from $1,350 to $1,285, and besides the touring body, a roadster has been added at the same figure.

The greatest change in the big car is in the outward appearance, which has been enhanced by sloping the cowl to meet the sloping bonnet. The price has been reduced $175 to $2,975. This is with seven-passenger body, the five-passenger having been dropped.

Since it was first brought out, the four has had only one mechanical change, that being the shifting of the front axle 2 inches forward, making the wheelbase 112 instead of 110 inches. This brings the axle in line with the radiator instead of back of it, though it has no effect upon the body dimensions. The front spring length has been affected by the change also, these springs now being 35 1-2 inches long, 1 1-2 inches greater.

There is no alteration in the distinctive valve-in-head, block unit power plant which is 3 1-2 by 5. The most unusual feature of this engine is that all parts of valve mechanism are inclosed. An aluminum plate goes over the rockers in the detachable head, and the long rods extending up from the camshaft are in a housing integral with the cylinder casting. The Delco system, which gears to the flywheel for starting and is driven from a shaft when operating as a generator, is employed.

The clutch is a cone type, a torsion tube encloses the propeller shaft, and the axle is floating. The most striking part of the smaller Oldsmobile is the excellent finish which has been given it. The appointments and equipment leave nothing to be desired. Circassian walnut is used for the cowl dash and for the steering wheel, for example.

The big car has a 139-inch wheelbase, and the chassis has been hung 2 1-2 inches lower, which adds to appearance. The cooling system has been augmented by a larger radiator and bigger waterjackets. The motor is 4 1-4 by 5 1-4, with cylinders in threes and gearbox in unit. The Delco electrical combination is used, as are cone clutch, open drive shaft fitted with two universals, floating axle and 36 by 5 tires.—Olds Motor Works, Lansing, Mich.

Overland Adopts Left Drive

The production policy of Willys-Overland has been broadened this year to take in three models, two fours and a six. The smaller four and the six are new.

All models have much the same general outward appearance, the bodies being of the present-day sloping hood type with cowls rounding down to the point where the bonnet begins. Although the six does not conform to the general design features of the four-cylinder engines, the final drive system is characteristically and uniformly Overland in all three. The three-speed gearbox is mounted in unit with the axle, and the propeller shaft is enclosed with a torsion tube having a yoked front end. The 1915 models are also the first to have left drive, though center control has been fitted on previous models.

One feature of the larger four and the six is the centralization of the electrical control switches in a box attached to the right of the steering column, 2 inches below the wheel. This carries the switches for all lights, for the starting current and also for the magneto. All models have electric cranking and lighting this year at the prices given, while their equipment is unusually complete.

Referring to the new six, the motor is a 3 1-2 by 5 1-4, L-head, block type, new to Overland design. Valves are on the right, compactly housed, and the cylinder head is removable allowing for ready inspection of valves and pistons. This car utilizes the Stewart vacuum fuel feed system, the tank being placed on the front of the dash and making more positive the flow from the main tank which is under the front seat. Wheelbase is 125 inches, tread 56, and rear spring suspension is three-quarter elliptic with the springs underslung from the floating axle.

The smaller four carries a characteristically-designed Overland motor with cylinders cast separately of L-head design and 4 by 4 1-2 size. It develops 30 horsepower, and is suspended at three points. Its clutch is a cone, the rear axle floating and the rear three-quarter elliptic springs underslung from it. Wheelbase is 106 inches and tires 33 by 4.

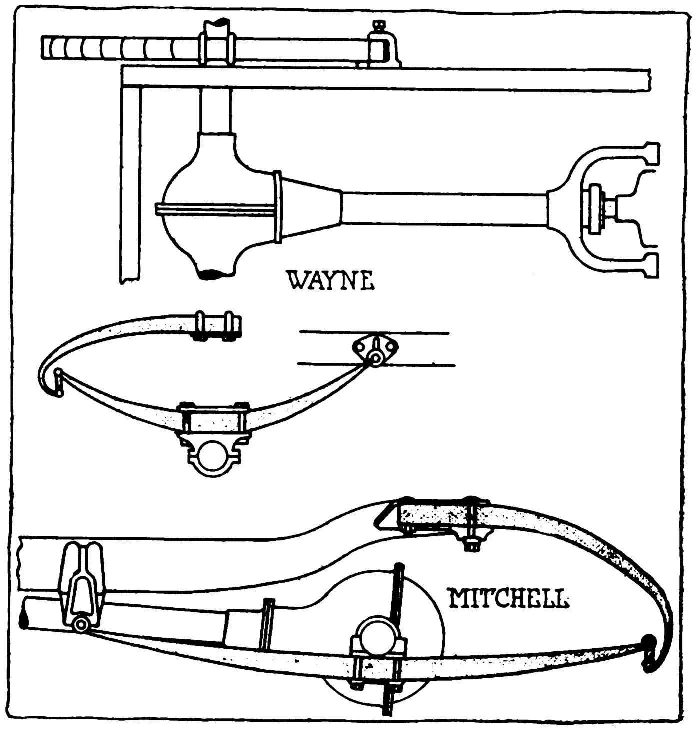
The larger four, with a similarly designed engine of 4 1-8 by 4 1-2 size, has a greatly enlarged body as compared with model 79 which it succeeds, though the wheelbase is the same, 114 inches. This greater roominess of body has resulted in larger seats, the rear now being 49 inches wide inside, and the front measures 40 inches across, and has a division.

The starting and lighting system has been remounted so that instead of driving the engine through silent chain, the starter gears to the flywheel. By underslinging the rear springs and redesigning the front axle, the body of model 80 is 3 1-4 inches lower than model 79. This model also has cone clutch and floating rear axle.

Although only a touring body is at present offered on the six, the model 80 four has roadster and coupé bodies as well as the five-passenger, while a roadster is also fitted to the smaller four. Delivery bodies may also be purchased for these four-cylinder chassis.—Willys-Overland Co., Toledo, O.

Owen Uses Entz System

R. M. Owen has incorporated the Entz electric transmission in a six-cylinder chassis which he is marketing for $3,750 in seven-passenger touring and three-passenger roadster design. The feature of this car is the use of the electric drive which replaces the clutch and gearbox. In the Entz system of electrical transmission, the patents for which are owned by the R. M. Owen company, a generator and a motor are combined in an unusual manner. The casing of the generator which carries the fields of whole pieces is bolted to the crankshaft replacing the flywheel. The armatures of the two machines are coupled together and their connecting shaft is permanently fastened to the drive shaft of the entire chassis.



Upper—Plan view of rear construction on Wayne. Middle—Side elevation of Wayne rear spring suspension. Lower—Rear suspension employed on the Mitchell

The speed of the car is regulated by the throttle in the customary manner but the torque for different loads is varied by changing the field strength of the generator and on lower speeds, by sending the generated current to the motor. When the car is running along under conditions similar to high gear, for a mechanically driven car, the generator winding is short-circuited on itself and therefore, with a slight amount of slipping the heavy current is generated. This current is of sufficient strength to create a magnetic attraction between the field and the armature equal to the torque required to propel the car at that speed.

The slippage varies with the torque so that if a slight grade is encountered the difference will become slightly greater, thus increasing the voltage of the generator, which will in turn produce a stronger magnetic attraction and the torque will become greater. Seven speeds are provided.

The motor fitted to the new car is a six-cylinder Weidely 3.75 by 5.5 I-head block. It is cooled by pump water circulation, oiled by pressure and has a dynamo-battery ignition system. The electric transmission is located amidship and final drive is obtained by spiral-bevel gear to a floating rear axle.—R. M. Owen Co., N. Y. City.

Packard Alters Carbureter

Packard has the same two sixes which have been sold since last July, namely the 3-38 and the 5-48. They are very much alike in appearance and in mechanical construction, although the latter is more powerful. Both conform consistently to the general Packard outlines with the distinctive radiator and sloping bonnet meeting a cowl construction which unites body and hood. There is a long list of bodies fitted to either chassis, and they do credit to the extensive body shops of the plant.

The general chassis construction is still characteristically Packard, the design being on the two-unit principle. The main unit is the motor and clutch, and the other the rear axle assembly, comprising gearset, final drive and differential gears.

Motors are practically identical with those used in previous cars, and are L-head types with cylinders in blocks of three. The 3-38, a 4 by 5 1-2, has an S. A. E. rating of 38 horsepower, and the 5-48 with the same stroke, has a 4 1-2-inch bore, and is rated at 10 horsepower more by the same formula.

Though of the same operative design, the carbureter body has been changed to give a housing for the auxiliary air valve, and the opening in the housing is turned to the rear to reduce the possibility of dirt entering.

A minor change which is distinctive is the use of headlamps of double design. Below the main headlight and integral with it is a smaller auxiliary headlight. This is useful for city driving or for meeting cars on the road, and is also advantageous for illuminating the road close to the car, since it is lower to the ground than the searchlights, which are better for distance. A refinement to be appreciated is the tool compartment in the left front door, which has a place for each tool. A leather flap goes over the kit.

Going into details of the 3-38, minor changes are the increasing the radiator capacity, enlarging the gearset proportions though the design is unchanged, and the increasing of the valve diameter from 2 to 2 1-8 inches.

The 3-38 wheelbase is 140 inches, and the overall length of the seven-passenger car is 187.5 inches. In the motor, the double exhaust system is retained, wherein each three cylinders gets rid of its burned gases through a separate passage, though the two passages are integral.

The Packard-Bijur system of cranking and lighting is employed and is of two-unit type, both being located on the right. The cranking motor gears 19.5 to 1 to the flywheel, and the generator, driven by shaft at 1 1-2 times engine speed, charges at 10 miles per hour, reaching its maximum at 15.

The drive is through a dry-plate clutch, then an open propeller shaft fitted with two universals to the gearbox which gives three forward speeds progressively. The axle has the new type of worm-bevel gears which give a rolling contact that practically eliminates noise. Rear three-quarter elliptic springs are underslung from the axle.

The 4-48 has a 144-inch wheelbase and incorporates practically the same design throughout as the 3-38 with the advantage of greater power. Tires are 37 by 5 all around; cooling water capacity is slightly greater, and front springs a trifle longer.—Packard Motor Car Co., Detroit, Mich.

Paige Has Cantilever Spring

The Paige-Detroit has been one of the later concerns to bring out a six, its model of this type coming to the front late last year. The entire line is made up of the six and a four.

Mounted on a 124-inch wheelbase chassis, the new six has capacity for seven in a body of advanced streamline type and is really designed along the lines of some of the European cars, its cowl having an almost flat slope to the bonnet which also slopes very slightly to the radiator. The body edges are rounded over and the upholstery is entirely inside, none protruding over the edges. The motor is a 3 1-2 by 5 1-4 unit power plant type of compact design.

Mechanical features include cantilever rear spring suspension, the spring having a 48-inch length. Drive is through multiple-disk clutch to three-speed gearset carried on a yoke which spreads around the flywheel. The propeller shaft is open, has two universals, drive being through springs and torque arm. The axle is floating and its ratio 4.07 to 1. Other features include Gray & Davis lighting and cranking, Bosch magneto, centrifugal pump cooling, left drive, center control, 15-gallon cowl gasoline tank and 34 by 4 tires on demountable rims.

The four-cylinder 36 is equipped with a 4 by 5 L-head motor of block type, with valves on the left. The gearbox bolts to a form of yoke which passes around the open flywheel similarly to the six-cylinder design in this respect. Other motor details are positive water circulation by centrifugal pump, Bosch ignition and Gray & Davis two-unit lighting and cranking, the latter function being accomplished through gear connection to the flywheel.

A Paige distinguishing feature is the use of elliptic rear springs which make for great resiliency. The axle is three-quarter floating and its housing is of malleable construction. A gear ratio of 3.79 to 1 is used.

The cowl gasoline tank fuel system has been a Paige feature for several years, and on the later 36's the filler has been placed on the cowl board.—Paige-Detroit Motor Car Co., Detroit, Mich.

Partin-Palmer Without Change

Two models known as the 38 and 20, both of which are fours, are continued by the Partin-Palmer company. The smaller model 20 listing at $495 with its four-cylinder L-head block motor, 2.75 by 4 inches, is a typical small car. It is mounted on a chassis of 96 inches wheelbase and standard tread with left drive and center control. The price quoted includes electric lighting with double bulb headlights and electric cranking is supplied for an additional $75.

Ignition is by the Atwater Kent distributer in connection with current either from the generator or storage battery. Automatic spark advance is supplied in the Atwater Kent distributer. The remaining features of the car are all of standard construction. The drive is taken by a leather-faced cone clutch through a three-speed gearbox and a floating axle. Liberal use has been made of nickel steel in the gearset, differential and axle shafts. The gears are of chrome-nickel steel.

The Partin-Palmer 38 is designed along the same line as the smaller model having a 3.75 by 4.5 motor and mounted on a 115-inch wheelbase chassis. Like the smaller car it has Atwater Kent ignition, a Stromberg carbureter, and at $1,100 is supplied with Gray & Davis lighting and starting. Without the starter the price is $125 less. The clutch is a cone and the gearbox provides three speeds. The tires are 33 by 4. This car is made only in a six-passenger touring body, while the smaller car is made in touring and roadster form. The small roadster incorporates a rear deck which serves as a tire support.—Partin Mfg. Co., Chicago, Ill.

Paterson Increases Valve Size

A six-cylinder touring car, the first of this type to bear the Paterson name, and the four-cylinder model, reduced from $1,197 to $1,095, are listed. The four, which was the only chassis made last year, has the motor redesigned for greater power, though its cylinder dimensions are unchanged. In addition, it has a floating axle instead of a semi-floating type and appears with a streamline body.

Both models are sold in one touring car body type, and this is much the same in line for four and six, the latter being somewhat larger. The running boards are clear, and in the front left door there has been placed a compactly-arranged tool compartment, with a special place for each tool.

The new cars are much the same in mechanical design and are fitted with 3 1-2 by 5 Northway unit power plants which are L-heads and block cast. The cylinder heads are detachable, and the upper half of the crankcase is cast integrally with the cylinder block. They have combination Delco electrical units for lighting, cranking and ignition, are fitted with cone clutches, left drive, center control, floating axles and drive through torsion tubes which surround the propeller shafts.

Valve diameter is increased from 1 9-16 to 1 5-8 inches, and better reciprocating parts balance and lighter weight make possible the greater operative speed, which goes as high as 2,500 r.p.m. The pistons have been crowned to give them greater strength with lightness and multiple thin steel piston rings, three to each groove, have been added as a factor for reducing to a minimum gas leakage past the pistons.

The Stewart vacuum fuel feed system is fitted to the six only. The vacuum tank is placed on the end of the exhaust manifold so as to give good gravity feed almost straight downward to the carbureter.—W. A. Paterson Co., Flint, Mich.

Pathfinder Refines Bodies

Few changes of a mechanical nature are to be found on the two sixes which will make up the 1915 Pathfinder line. They are the same two sixes as were marketed last season with a number of body refinements. These changes are principally to be noted in the roadster, which is a new streamline design having a covered rear compartment fitted with a little door through which packages may be inserted. The rear compartment also contains folding seats for two extra passengers. The larger goes under the name of Leatherstocking, while the smaller is known as Daniel Boone. The Leatherstocking is made only as a seven-passenger, and the Daniel Boone in seven-passenger and roadster style. For this season Westinghouse lighting and starting is used.

These cars carry the Continental six-cylinder power plants of 3.75 by 5.25 and 4.125 by 5.25 inches respectively. The design of the two models is similar, both being L-heads with the cylinders cast in threes. They both have inclosed valve mechanism and three-point suspension. No changes in prices have been made, although both cars have been considerably refined as regards their bodies and equipment. The five-passenger touring Leatherstocking sells for $2,750; the Daniel Boone $2,222.—Motor Car Mfg. Co., Indianapolis, Ind.

Peerless Lightens Chassis

In addition to the continuation of its big model 48-six, the Peerless company has brought out a much lighter four and six, calling them all-purpose cars. These new cars present attractive outward appearances, being of the streamline form. Practically the same design holds for the four and the six, though the latter has certain larger dimensions, naturally. One body feature which is new is the dividing of the front seats into individual armchair types, a passage running between them, giving access to the tonneau.

The motors conform to the same general design throughout. They are of the L-head, unit power plant construction, carried at three points. In both cases the cylinders are in block form, and dimensions are nearly the same. The six has a 3 1-2-inch bore and the four is 3 3-4, but the stroke is uniform at 5 inches. Ratings are 29.4 and 22.5 horsepower, respectively, by the S. A. E. formula, but the engines are said to attain 2,000 r.p.m. when the developed power is 38 and 50.

Stromberg carbureters are fitted, and ignition is by Atwater-Kent Unisparker system. The motors carry Kellogg single-cylinder tire pumps, driven from the generator shaft, as well as Stewart vacuum fuel feed tanks. Gray & Davis cranking and lighting are also used, there being separate cranking motor and generator, the latter being driven by a shaft from the front gears, and the former drives the engine through gear connection to the flywheel. An 80-ampere Willard battery is a part of the system.

Throughout the drive, modern features are in evidence, such as open drive shaft of two-universal type which is of tubular form in the center. Its power comes through a multiple-disk clutch, and it delivers it to a semi-floating axle, the main housing of which is reinforced pressed steel. Platform rear spring suspension which has always characterized Peerless cars is in evidence on the new pair. Tires of both cars are 34 by 4, and the six wheelbase is 121 and the four 113 inches.

The big six, model 48, carries a 4 1-2 by 6, T-head engine with cylinders in pairs, has Bosch ignition, Peerless carbureter, Gray & Davis cranking and lighting, and splash lubrication. Its wheelbase is 137 inches, driveshaft fitted with two universals, and floating axle. The rear spring suspension is of the platform type. Tires are 37 by 5, and options of right drive and control, or left drive with center control are allowed. The prices remain $5,000 for touring car, and $4,900 for roadster with all equipment and up-to-date bodies.—Peerless Motor Car Co., Cleveland, O.

Peter Pan Has Cantilevers

Peter Pan is the name given to the new car put out by the Randall company. It is made in four-passenger touring and two-passenger runabout bodies on the same chassis. The wheelbase is 110 inches and although this length is as great as in some of the heavier cars, everything about this new product has been made along light lines.

The four-cylinder power plant has its 2.75 by 4.5 cylinders cast in a single block with the valves in the head. Cooling is thermo-syphon through a tubular radiator. A Berling magneto is the sole source of current for ignition and for starting a mechanical device is relied upon.

A multiple disk clutch transmits the drive through a three-speed selective sliding gearset. Control is in the center and the steering wheel on the left. The springs are floating cantilevers and the brakes, as regards the service set mounted on the transmission shaft, with the emergency brakes on the rear wheel. The bodies are streamline adaptations and carry out the up-to-date scheme of deep upholstery and full equipment.—Randall Co., Norfolk Downs, Mass.

Pierce Drops Chassis Frame

Only one change of any importance has been made in the primary design of Pierce-Arrow cars. This has been a drop in the central portion of the frame. With this single change the entire appearance of the new line has been altered and in connection with its adoption it has been necessary to make one or two other minor alterations. The first of the latter is the abandonment of the gravity gasoline feed and the substitution of a pressure system with the tank at the rear of the chassis. In turn the adoption of pressure has rendered possible the raising of the carbureter with a consequent shorter intake manifold.

With but one exception no change has been made in the prices. The largest limousine on the 66 chassis, which is the largest of the three sixes which compose the Pierce line, has been reduced from $7,100 to $7,000. On account of the drop of the frame which has been made on all three models it has been found possible to lower the bodies and running board without reducing the road clearance.

There are also a number of other minor changes for the convenience of the driver. The control members, including the excellerator, throttle and spark control, have been simplified. The engine cannot be started if the bonnet is locked and the key removed from the ignition switch.

Fifty-four body types and an unlimited number of color schemes is the Pierce offering in the way of carriage work. In addition to the different body designs and the general improvement in appearance because of the drop frame the Pierce company states that the new models have more power, better pick-up and higher speed because of the pressure feed gasoline system. The new fenders are wider, a one-man top has been fitted and individual front seats are provided on the regulation touring cars.

All three Pierce-Arrows are built along similar lines. The chassis are known as 65 A-3, 48 B-3 and 38 C-3. The power plants are 5 by 7, 4.5 by 5.5 and 4 by 5.5 inches. All have their cylinders cast in pairs and the T-head design has been maintained to provide for the large valve area with the shortest possible over-head length. Seven bearing crankshafts are used and on the camshafts the cams are pinned

to the shafts. The electrical equipment is provided by Westinghouse.—Pierce Motor Car Co., Buffalo, N. Y.

Pilot Adds a Six

Three sixes are made by the Pilot Motor Car Co. One of these, the 55 is an entirely new addition to the line and takes the place of the four manufactured for the 1914 season. The other two, known as the 75 and 60 are continuations.

The new six is the Pilot leader for this season. It is built on a chassis of 126-inch wheelbase and is provided with either two or five-passenger body and at an additional price a seven-passenger. It has a 3.5 by 5.25 T-head power plant and is fitted with the popular cantilever springs. The 75 has a 4.5 by 6 and the 60, a 4 by 6 T-head motor. The wheelbases of these two are 132 inches.

Chrome nickel steel piston pins secured in the upper ends of the connecting-rods, are used. The bosses in the pistons provide the bearing surface and the makers claim that by so doing they have gained a higher percentage of bearing surface as compared with the practice of fixing the pins in the piston boss. Drop forge carbon steel connecting-rods and crankshafts are used and the bolts holding the connecting-rod caps in place are nickel steel. The aluminum crankcase carries the main bearings on bridges allowing bearings adjustment to be made by dropping the bottom pan of the motor. The bearing material is die-cast nickel babbitt.

A patented lubrication system is used on all Teetor motors, the Pilot being fitted power plants of this make. There are two overflow oil basins into which the connecting-rods dip, these being fastened in the lower half of the crankcase. In the bottom of these two oil troughs there are drilled oil holes which are of just sufficient size to admit a definite quantity of lubricant. As the oil is circulated by the connecting-rods it is replaced by the oil supplied through these holes giving a system which is claimed to feed in a direct ratio with the motor speed. The reservoir is in the bottom of the crankcase.

The clutch and gearbox are Warner products. The clutch is a cone and the gearbox provides three speeds. They are contained in a unit housing forming a unit power plant. The drive shaft has two universals and the axle is floating.—Pilot Motor Car Co., Richmond, Ind.

Pratt Concentrates on a Six

The Elkhart company, makers of the Pratt automobile, are concentrating on a new six which they have just brought out. This is the sole model made by this concern for 1915. This chassis will be equipped with five different body designs, a two-passenger, four-passenger, five-passenger and seven-passenger. It has a 3.75 by 5.25 Continental motor in a unit power-plant with three-point suspension. The gearbox provides four speeds and is of Brown-Lipe manufacture. The carbureter is the latest Rayfield.

The drive is taken from the gearbox by a horizontal shaft with a Spicer universal joint at either end. The rear axle is a Timken and full Timken equipment is also provided in the front axle. The electrical equipment of the car consists of a Gray & Davis starting and lighting system with battery ignition through an Atwater Kent distributer.

Left drive is used and center control, the gearshifter lever being mounted directly on the cover of the gearbox. The equipment of the car is complete, non-skid tires being furnished for the rear and a one-man top, keyless clock, bumper rail, power tire pump are also included. The body is of streamline characteristics provided with wide doors.—Elkhart Carriage & Harness Mfg. Co., Elkhart, Ind.

Premier Continues Weidely

The six-cylinder overhead-valve Weidely motor still is featured by the Premier Motor Mfg. Co., Indianapolis, Ind., while a second car in the line is the model 6-49 equipped with a T-head engine. The substitution of long semi-elliptic rear springs for three-quarter elliptic is the only change made for the year.

In the Weidely motor the valves are set directly in the cylinder head, getting away from valve cage construction. No rocker arms are used but instead a single camshaft is mounted above the valves and the shaft operated by worm gearing. The worm gear is attached to the center of the camshaft and another gear in mesh with it is fastened to a vertical shaft which is driven directly from the crankshaft.

The valve stems are not touched directly by the cams, but what are called fingers are placed between the two. These fingers merely are levers pivoted at one end and move up and down with the movement of the valves.

The wheelbase of the Premier-Weidely is 132 inches, the clutch a disk, and the gearset a three-speed selective driving an open shaft to a floating axle. Remy cranking and lighting is used but ignition is by an Eisemann instrument. Three body styles are offered, a roadster, and a five-passenger at $2,700 and a seven-passenger at $2,750.

The 6-49 Premier has a T-head, 4 by 5 1-2 motor which develops unusual power, the figure being 70 horsepower maximum, it is claimed.

Triplet casting of the cylinders is used and the blocks are set close to one another so as to decrease the crankshaft length and hence the distance between bearings for the sake of rigidity. In the top of the castings there is the camshaft chamber which is completely covered by an aluminum plate which seals the upper ends of cylinder water jackets.

The drive is similar in design to that of the Weidely chassis. In five-passenger form this car sells for $2,385.—Premier Motor Mfg. Co., Indianapolis, Ind.

Pullman 4 Inches Longer

Two models, a six and a four will compose the Pullman line for this season. The six, is the 6-48 in practically the same form as was introduced at the 1914 New York show. The four, is an entirely new model and will be known as the junior.

Some refinements have taken place on the six, the main one being the increase in wheelbase of 4 inches, bringing it to 134. This of course has necessitated a larger body and a strengthening of the spring suspension although in general the car is of lighter structure than for last season. The larger body has been utilized to provide 2 inches more in the driver's compartment and 6 inches more in the tonneau. The seats have been widened and deepened and the rear doors carried back further. The dash is now covered with leather and the instrument for the 12-volt electric system mounted on the cowl board. The radiator is lighter but has a larger cooling capacity and the price remains the same with Vulcan electric gear shifting at $150 extra.

The new Junior model has been made to meet the demands for a light four-cylinder vehicle selling at a low price. The price in either touring or roadster design being $740. The motor is an L-head block with 3.75 by 4.25 cylinder with the valves on the left side. The crankshaft is carried on three plain bearings and the camshaft driven by silent chain. The motor clutch and gearbox are included in a unit housing and suspended at three points. Cooling is by thermo-syphon.

The gearbox provides three speeds with a ratio of 4 to 1 on direct. The steering wheel is on the left side and the control in the center. The rear spring is a cantilever, the wheelbase 110 inches and tires, 33 by 3.5.

The power plant of the six has its cylinders cast in threes. It is an L-head 3.75 by 5.25 design of which the makers claim 38 horsepower at approximately 1,500 r.p.m. on the block. The clutch is a multiple disk and is a part of the unit power plant. Lighting and starting is taken care of by the Westinghouse system and the dash equipment is carried on a cowl board. The 20-gallon gasoline tank is mounted beneath the cowl.—Pullman Motor Co., York, Pa.

R. C. H. Improves Equipment

A five-passenger touring car of streamline appearance represents the R. C. H. for 1915. The body lines are unaltered, but the front seat has been moved 1 inch further back, so as to give more leg room. In the equipment, a one-man top supplants the older style with forward and rear supports. Mechanically, the car is unchanged.

The R. C. H. has a 3 1-4 by 5 block-cast L-head engine. The cone clutch is provided with a brake that applies automatically when the pedal is pressed, thus stopping it from spinning, facilitating gear changes without clashing. The gearset is of the three-speed type, and delivers its power to a rear axle having a reduction of 4 1-4 to 1. The wheelbase is 110 inches and this allows room for a comfortable five-passenger body. The running boards are clear, door hinges and handles are concealed and the equipment adds to the whole. Among this may be mentioned rain-vision ventilating windshield, 32 by 3 1-2-inch tires on demountable rims and speedometer.—R. C. H. Corp., Detroit, Mich.

Regal Drops Underslinging

Concentration upon the construction of one overslung chassis is the 1915 policy of the Regal company, this being a new model. The underslung model sold in 1914 has been dropped. Thus the new chassis marks the passage of the underslung construction from the Regal shops, the same low center of gravity now being obtained by springs hung from the under side of the axle. The new Regals are fitted to a 112-inch wheelbase, and bodies are of the sloping hood and cowl type, fenders being domed and running boards clear. Wide doors with concealed hinges and latches do their part in appearance.

The motor, 3 3-4 by 5, is a block type L-head form with cylinder head detachable and exhaust manifold cast integrally with the main casting. This engine is 150 pounds lighter than that of last year's underslung car. Better balanced and lighter reciprocating parts are one factor, and the use of a steel stamped lower crankcase portion in place of a cast iron type is another. The use of multiple thin steel piston rings is a new feature.

Spark and throttle levers have been replaced on the steering wheel. Atwater Kent ignition of automatic advance type makes a spark lever unnecessary, and control of the carbureter is mainly by the accelerator. However, a hand lever control is placed on the cowl dash so that the engine may be set at any desired minimum speed.

An innovation is the placing of the radiator filler cap under the hood; it now being a part of the outlet connection from the waterjacket. This prevents spoiling the hood and radiator finish by spilling water on it.

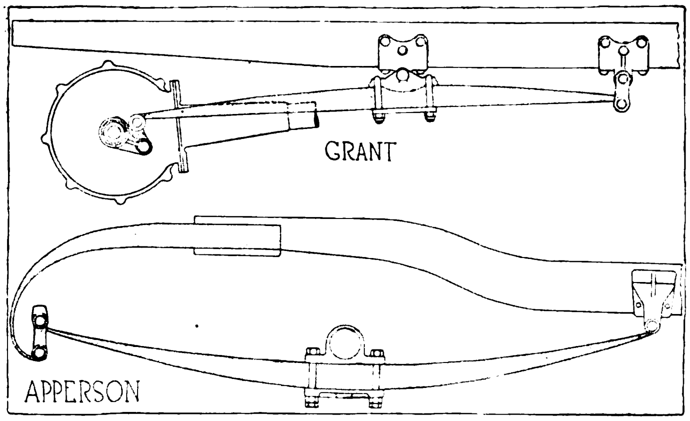
A Bosch-Rushmore two-unit system of cranking and lighting is employed, the cranking motor gearing to the flywheel, whereas the generator is carried on the right forward side of the engine and has a unique belt drive. A pulley on the end of the crankshaft runs over both the fan pulley and generator pulley and provision is made for adjusting its tension.

A three-quarter floating axle with 4 to 1 ratio replaces a heavier half-floating type used on former Regals, the front axle being also lighter. Tires are 32 by 4.—Regal Motor Car Co., Detroit, Mich.

Remington a New Light Four

The Remington four-cylinder chassis makes its appearance this season in roadster and touring bodies. The chassis upon which both cars are mounted is the same with the exception that 30 by 3.5 tires and demountable rims are used on the touring, while the roadster has 30 by 3 tires with clincher rims.

The motor is a four-cylinder block-cast 3.125 by 4 unit power plant with three-point suspension. All the valves are on the right side and are enclosed by a detachable cover plate. The valve diameter is 1.5 inches in the clear with a 3-16-inch lift. The piston length is 4.5 inches, connecting-rods 10.5 inches, with a .875-inch piston ring of 1.75 inches length. The crankshaft is carried on two main bearings and has a diameter of 1.75 inch. The camshaft is also carried on two bearings and has a 1.25-inch diameter.



Upper—Diagram of cantilever spring suspension employed on the Grant. Lower—Similar illustration of the Apperson rear suspension

Lubrication is accomplished by splash, ignition by the Atwater Kent distributer system and starting and lighting by Ward Leonard installation. The clutch is a cone and the gearbox provides three speeds operated by an automatic gearshifter. The spark control is also automatic having the centrifugal arrangement in the distributer.

The rear axle is a three-quarter floating type with bevel gear differential made of nickel steel. The bearings in the rear axle are Hyatt high-duty type while in the front wheels the Bower rollers are used. The front axle is an I-beam drop-forged. The wheelbase for both cars is 106 inches.

Both the touring and roadster bodies are fully equipped. The dash is of Circassian walnut with all the instruments mounted upon it. A long cowl is used and advantage is taken of its length to house the gasoline tank which has a capacity of 12 gallons. In the touring body a robe rail formed by an adjustable strap is used.—Remington Motor Co., New York City.

Reo Adds a Six

The Reo Motor Car Co., Lansing, Mich., which has always been regarded as a one-model concern with its four-cylinder Reo the Fifth as its sole representative, has this year placed upon the market a six, in addition to continuing the four in improved form. In general, the new Reo adheres to the same design as that of the four, and is characteristically a Reo throughout.

Some of the special constructional features of this new six, which has 122-inch wheelbase, are the spiral-bevel gears used in the floating rear axle and the cantilever rear springs which are attached to the frame and axle housing in the regular way. In addition to body improvements in the Reo the Fifth which make for better upholstering and more roominess, there are such important alterations as the increase of the wheelbase from 112 to 115 inches, the use of a new cylinder design with independent exhaust ports, the addition of friction surface to the disk clutch, the non-rattling support of the brake mechanism and the improved starting mechanism doing away with shifting of gears.

The motors of both Reos adhere to the distinctive construction characteristic of these engines wherein the inlet valves are placed in the head and the exhausts on the side. The six is a 3 9-16 by 5 1-8 engine with 40 to 45 horsepower rating and cylinders in threes. The four has 30 to 35 horsepower with 4 1-8 by 4 1-2-inch cylinders in pairs. Crankcases are of the barrel form of aluminum, and helical timing gears are employed as well as exhaust manifolds of the ejector type which reduce the back pressure. Crankshafts and camshafts are supported on three bearings.

Ignition, cranking and lighting for the two models is uniform, the ignition distributer being combined with the generator with the storage battery as its source of current. The starting motor connects in the gearset to the mainshaft through worm gear construction.

The clutch used is a dry disk type which is changed from that formerly used by giving it more friction surface, and by a new operating mechanism which requires less foot pressure.

Streamline hub caps, so called are fitted on the new Reos. These are simply smooth, domed housings for the spindle nuts which are held in place by a set screw to coincide with the lines of the body.

The drive construction of the six terminates in a floating rear axle, while that of the four is semi-floating. The brake rods and parts are fitted with anti-rattlers which aid in silencing the cars. Gearsets are of the three-speed, selective design and gasoline tanks are carried under the front seat, feeding by gravity.

In addition to standard equipment, the six carries a motor-driven tire pump driven from the clutch shaft with the hose permanently connected to the pump and placed in a special compartment in the body.—The Reo Motor Car Co., Lansing, Mich.

Republic Adopts Vacuum Feed

The Republic line of one model is continued without change as far as the makeup of the output is concerned. Several detail changes are worthy of note, particularly in the employment of the new vacuum feed system for gasoline and in the adoption of the Rayfield carbureter as standard equipment.

The power plant remains the same in every respect, the six T-head cylinders being cast in pairs. The dimensions of the cylinders are 4.25 by 5. The water is circulated by a pump, oiling is by a pressure system in which a gear pump takes the oil from the crank case and forces it under pressure to the main bearing. From these points it is carried through the drilled crankshaft to the lower connecting rod bearings.

The entire electrical equipment is furnished by Delco. This is a dual system and not only takes care of ignition but also of lighting and cranking. The wiring is double and the voltage of the system, 7.

The clutch is a leather cone in the flywheel and the gearset is a four-speed selective located amidships. Final drive is by shaft to a bevel gear, floating rear axle which delivers the propulsive thrusts through radius rods. The wheelbase remains the same as last year at 133 inches.—Republic Motor Car Co., Hamilton, O.

Saxon Six Introduced

From the enlarged factory of the Saxon company, a six-cylinder machine is now coming forth which sells at $785, this in addition to the four-cylinder roadster in improved form at $395. The six is seen for the first time at the show, and is said to be the lowest priced six in the field. Factory expansion has resulted in the plans of the company to double its output of the four, in addition to building 25,000 of the sixes, on which the price is based.

The two Saxons adhere to the same general construction throughout, though the six has larger proportions and certain differences incident to its greater power and weight. The motors are L-heads, cast in block with multiple, dry disk clutch in unit. The six has a 30 to 35 horsepower motor, 2.875 by 4.5, and the four-cylinder is a 2.625 by 4 size. They have Atwater-Kent ignition, thermo-syphon cooling and fuel feed by gravity from gasoline tank carried in the cowl.

Other features include gearset in unit with the rear axle and cantilever springs all around. The six is provided with three forward speeds, while the four has two, and another difference is in the type of rear axle, that of the little car being a semi-floating construction whereas its bigger brother is fitted with a three-quarter floating design.

Brakes are on the rear wheels, operating in the usual way through pedal and lever. Steering is on the left and control in the center. Hyatt bearings play an important part in the rear construction of both cars.

The six has an unusually long wheelbase for a car of its price, the figure being 112 inches. The four is of 96-inch wheelbase. Tires are 28 by 3 on the four, and 32 by 3 1-2 on the six.

The six, which comes in five-passenger touring car form only, is well equipped. It has Gray & Davis electric lighting and cranking equipment, demountable rims, top, windshield, electric horn, speedometer, one extra rim, tools and tire irons at the price. To give some idea of the roominess of the body, the front seat is 41 inches wide; the rear seat 47 inches; and the distance from the heel board to the dash is 28 inches.

The four-cylinder car, which is a roadster only, is fitted with electric lighting and cranking at $70 additional. This is a refined car as compared with the original Saxon brought out about a year ago, and appeared in its present form the latter part of last July. Larger body of streamline form, which is roomier and better-looking, and full running boards now grace this Saxon. Small changes include the placing of the gasoline filled plug on the dash instead of under the bonnet where it was inconvenient to get at, and the fitting of a three-hinged hood in place of the single-piece design. Headlights have been moved from the sides to the front of the car.

As compared with the original car, there is refinement in the rear axle also. Felt washers have been provided which prevent the oil from working out onto the brakes, and an oil filler in the differential carries the lubricant direct to the bearings. A through pin for locking the differential pinion carrier replaces a set screw.

The equipment takes in top, windshield, acetylene headlights, oil tail lamp, gas generator and horn.—Saxon Motor Co., Detroit, Mich.

Scripps-Booth Drops Cyclecar

To succeed the cyclecar which it brought out about a year ago, the Scripps-Booth Co., Detroit, has designed what may be regarded as one of the most luxurious types of automobiles in its class. This car as a roadster sells at $775 and is fitted with a four-cylinder 2 7-8 by 4 motor, has 110-inch wheelbase and is mounted on 30 by 3 1-2 tires.

Its equipment is of the most modern type, including motor-generator for lighting and cranking, Houk wire wheels with one extra carried on the rear deck, electric door openers, electric horn, 9-inch Turkish upholstery, attractive windshield, silk-mohair top and curtains.

Made with an option of three treads, 40, 56 and 60 inches, the chassis make-up takes in a cone clutch, three-speed gearset in unit with the motor, double rear wheel brakes, floating rear axle, tubular drive shaft, semi-elliptic front and cantilever rear springs and a frame which narrows to both front and rear in order to follow the curve of the body and thus give rigid support to it.

The S. A. E. rating of the engine is 13.25, but 19 horsepower is claimed for it. It is a high-speed type of power plant, running as high as 2,750 r.p.m. without much drop in the power curve. Silent operation has been attained by special cam design which allows the valves to drop within 1-1,000 inch of their seats and then slowly lets them down the remaining minute distance. The cylinders and crankcase are cast in one piece, and the head is detachable. It carries the valves and their rockers together with the passages to the intake ports. Two main bearings support the crankshaft, and three carry the camshaft.

Lubrication is of the circulating splash type, ignition is cared for by Atwater Kent distributer and cooling is by thermo-syphon. The motor-generator for lighting and starting is hung from an integral bracket on the right side of the crankcase. It connects to the crankshaft through silent chain, the sprocket for which is just ahead of the flywheel.

The car has a leather-faced cone clutch from which the power goes to the rear through a three-speed gearset in which unusually large gears with a 5-8-inch face width are employed. The tubular propeller shaft is 1 1-4 inch in diameter, and the drive is taken through the springs, a torque arm taking the torque.

Unusual features are the use of pedals for operating both sets of brakes, the clutch pedal taking care of the service set in addition to performing its clutch function. Steel cables take the place of rods for working both sets of brakes.

Push buttons placed close to the doors operate the latches magnetically, which is a point new to motor car body building. Throughout the car the aim of the designer has been to show that luxury may be had in the small car as well as in the more expensive. The idea is to make a car that will be approved by the fastidious.

Drive is on the left by a 16-inch walnut wheel, and control in the center. Besides the roadster body, a cabriolet and a coupé are fitted to the same chassis.—Scripps-Booth Co., Detroit, Mich.

S. G. V. Has Larger Chassis

One chassis upon which all types of bodies are mounted is made by the S. G. V. company. This is an entirely new model and has a 3.875 by 4.325 motor as compared with the 3.75 by 5 motor introduced last season. The new car has its four L-head cylinders cast in a single block with the valves on the right side. The single integral camshaft is driven by a silent chain and the valves are inclosed, giving a clean exterior appearance. Both the intake and exhaust manifolds are cast separately from the cylinder, the exhaust being ribbed according to the European practice which this car closely follows. The motor is supported at 4 points.

A centrifugal water pump in connection with a cellular radiator cools the motor and the fan is formed by the spokes of the flywheel. Another point at which European practice has been followed is in the pressure feed lubricating system in which a gear pump forces oil to every bearing even to the piston pins. Ignition is by a single system, a Bosch insulation with one set of plugs taking care of this function. The carbureter is 1.25-inch Zenith fitted with hot-air pipe and taking its feed by pressure from the 20-gallon gasoline tank located at the rear of the chassis. The Ward Leonard system is provided for lighting and starting.

The transmission system is made up of a disk clutch selective sliding gearbox providing four-speeds and a semi-floating rear axle with a bevel gear differential. The drive is taken through the spring. The wheelbase on the new model is 118 inches, the tires 34 by 4 and the tread standard. The body work is of European style especially insofar as the closed cars, namely, Limousine, brougham, landaulet and landau are concerned.—S. G. V. Co., Reading, Pa.

Simplex Has Three T-Heads

Simplex cars continue to be made in three chassis; a 38 shaft drive, a 50 inclosed chain or shaft drive and a 75 inclosed chain or shaft. The numbers serve to indicate the maker's horsepower rating as well as the model. The Simplex company manufactures only the chassis, the bodies being subject to order.

All three Simplex models have T-head motors supported at four points, dry disk clutches located in the flywheel and four-speed gearboxes mounted amidship and supported at four points. The 38 is a 4.875 by 6.5 with its cylinders cast in pairs, the manifolds are cast separate with the intake on the right and the exhaust on the left. The motor is water-cooled, a honeycomb radiator being used in connection with a centrifugal pump. Dual ignition is used. A Bosch high tension magneto being used as the current source. The balance of the electric equipment is a Bosch Rushmore outfit of the six-volt type operating with a single wire installation. The 28-gallon gasoline tank is operated by a pressure system and a Simplex carbureter is used as the vaporizing medium. A shaft with bevel gear reduction of 2.75 to 1 on fourth speed is used and the drive is taken through a torsion tube. The wheelbase of this chassis is 137 inches.

The 50-horsepower model which was new last year has been continued without change. It has a bore of 5.375 and a stroke of 6.5 inches. In general design it is similar to the smaller model described. The only difference is that if desired, a chain drive will be fitted. When the latter is the case, the propulsion is taken through radius rods while as with shaft a torsion tube serves this purpose.

The 75-horsepower model has the same sized cylinders as the 50 and in fact is the same throughout as the latter except tuned up for racing. The valves are larger. A steeper set of cams is used and a dual-double ignition system with two sets of spark-plugs are provided. Chain drive was of-

Bottom—Rear construction of the Speedwell, showing ingenious utilization of frame end for supporting spring shackle

fered in 124-inch wheelbase and chain or shaft in 137.—Simplex Automobile Co., New Brunswick, N. J.

Singer Has Cross-Head Piston

The Singer Motor Co. which has recently been formed has brought out a six-cylinder car fitted with a 4 by 5.5-unit power plant suspended at three points, dry-plate clutch and four-speed gearset with direct on fourth. The wheelbase is 135 inches and the tires are 36 by 4 5. A feature of note is the unusual method of marketing the car which will be directly from the factory to the consumer.

The large power plant which is a T-head design is stated to show 100 horsepower at 2,000 r.p.m. on the dynamometer; an advantage has been taken of this high power by gearing the direct drive 3.66 to 1. In the actual construction of the motor the cross-head pistons are the only departure from standard practice as far as the internal structure is concerned. On the exterior of the motor the novel design of the intake manifold will be immediately noted. Both the carbureter and the manifold are water-jacketed but the latter is especially notable for the large radius of its turns and the diameter of the pipe, which takes a 1.75-inch C. R. G. carbureter.

The exhaust manifold is designed with interior walls to avoid in any way difficulties which might be experienced by two cylinders exhausting at the same time.

The method of fastening the steering drop arm is a departure from standard practice, the hub being pierced with triangular slots corresponding to a similar opening in the shaft to which it fits. The shaft is then tapered so that adjustments for wear may be made by tightening the nut holding the arm in place. This is a patent of the Jacox company. The gear itself is a worm and nut having a 2-inch column and a 19-inch wheel.

A distinctive type of streamline body having unbroken lines from the pointed radiator to the moulded surface at the rear of the tonneau is fitted to the chassis. Left drive with center control is used and the one-piece design is carried out in such parts as the windshield, which is built into the cowl. The various instruments are carried on a cowl board and a fire extinguisher is an unusual addition to the equipment.—Singer Motor Co., Long Island City, N. Y.

Spaulding Underslung Rear

The single four-cylinder model H Spaulding chassis is continued with a number of improvements chief among which are the placing of the rear springs underneath instead of over the axle and the fitting of a body with more graceful lines. Aside from these changes the car is practically the same as before being fitted with a touring body which can be converted into one with sleeping quarters sufficient for five persons. This is done in a few minute's time by dropping the hinged back of the front seat. An electric reading lamp is provided in the compartment so as to make the improvised hotel room comfortable.

The chassis has a 120-inch wheelbase and is fitted with a Buda motor, 4 1-4 by 5 1-2. Ignition is by Simms magneto and cranking and lighting by the Entz system. The gasoline feed used is a pressure gravity system in which fuel is forced from a container at the rear to an auxiliary tank on the dash and thence to the carbureter by gravity.—Spaulding Mfg. Co., Grinnell, Ia.

Speedwell Has Rotary Valve

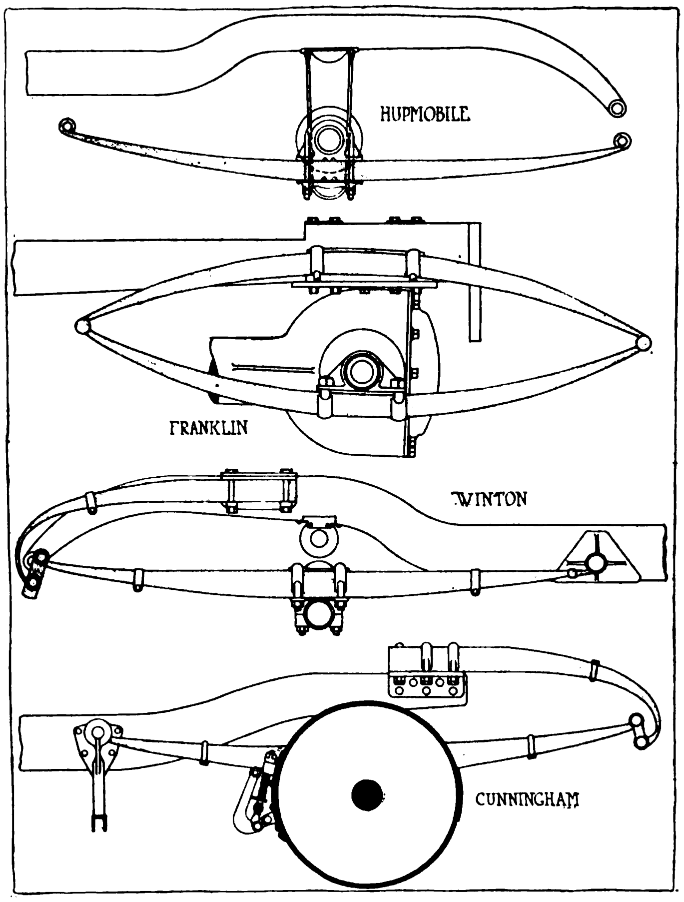
The Speedwell is continuing a single six-cylinder chassis fitted with a Mead rotary-valve motor, with only slight changes over the former model. The changes are, the adoption of the Westinghouse cranking, lighting and ignition system instead of that used previously, a Stewart vacuum gasoline system and changing the position of the instruments from the floorboards to a cowl dash.

The Speedwell is fitted with a Mead-type rotary-valve motor in which there are two valves for the six cylinders one on each side of the cylinder block. Each valve contains six slots and these register with slots which communicate with the inlet and exhaust manifolds. In order to assist in the lubrication of these valves they are grooved longitudinally and between adjacent cylinders the valve is fitted with a ring so that there will be no leaks from one cylinder to the other. The valves are made of gray iron and the cylinders of semi-steel so that wear will be reduced. Aside from the valve arrangement and the necessary changes in cylinder design, the motor shows no radical construction. Its dimensions are 4 1-8 by 5 1-4 and it drives through a disk clutch and three-speed gearset, a unit with it, to a Timken floating axle.

The Speedwell rotary is made with three body types, a four-passenger at $2,850, a five-passenger at the same price and a seven at $2,950. A six-passenger also is made by adding two auxiliary seats to the four. The chassis has a 135-inch wheelbase and tire sizes are 37 by 5 for the six and seven-passenger and 36 by 4 1-2 for the others.—Speedwell Motor Car Co., Dayton, O.

Sphinx Makes Light Four

A newcomer for this season is the Sphinx, a light four-cylinder car with a five-passenger streamline body mounted on a 112-inch wheelbase and having a four-cylinder monoblock power plant, three-speed gearbox and a roller bearing



Top—Diagram cf spring suspension used on the Hupmobile. Upper Middle—Full elliptic spring construction used on the Franklin. Lower Middle—Winton's method of attaching spring to side member of frame, showing use of frame end for shackle support. Bottom—Cunningham rear suspension

rear axle. It is thoroughly equipped with electric lighting and starting, and wire wheels may be had for $25 extra.

The motor has its 3.375 by 5 L-head cylinders cast with a detachable head. The power plant is featured by lightweight reciprocating parts and throughout is of high-speed design. The valves are of the orthodox 45-degree poppet type, having a diameter in the clear of 1.375 inches. The crankshaft is a 0.40-carbon steel alloy carried on two main bearings. The diameter of the crankshaft is 1.75 inches.

In connection with the generator a battery system of ignition is used, the high-tension distributor being operated from a vertical worm-driven shaft. Lighting and starting are accomplished by a single-unit motor-generator.

The lubricating system is a circulating splash, the pump being driven from a cam off the camshaft. A 1-inch carbureter fitted with hot-air intake and a shut-off valve for starting, is fed by gravity from a 25-gallon gasoline tank.

A 12.5-degree cone clutch, having a chrome leather facing with spring and plunger inserts for gradual engagement, transmits the power to a three-speed Covert gearbox located on the rear axle. The drive shaft, countershaft, and dog clutch of this gearbox are carried on roller bearings. The rear axle is a Weston-Mott carried on Hyatt bearings and the front axle is tubular with cup and cone ball bearings in the hubs. Control is central with the steering wheel on the left. The clutch and service brake are both operated from the left pedal. The emergency brake by the right pedal thereby eliminating all but the gearshifter lever.—Sphinx Motor Car Co., York, Pa.

Stearns Has Small Knight

The new four-cylinder Stearns-Knight type at $1,750 is one of the more interesting cars because this is a price almost $1,000 under any previous Stearns-Knight type and also the low mark for a Knight sleeve-vaive motor in this country. While the trend was toward sixes Stearns has been one of the several to bring out a small four in preference to a small six. This new model with 3.75 by 5.625 block cast cylinders incorporates many new, yet tried, features in motordom, including the crankshaft with counter balance weights to overcome centrifugal force, a specially light cylinder block embracing the intake and exhaust manifolds, and a light construction in the crankcase, the timing chain cover and other car parts by the use of stamping in such places where strength is not a primary consideration. In addition to the balanced crankshaft, designed to prevent appreciable wear on the crankshaft bushings, tubular connecting rods are used, these also being specially balanced at the lower ends by a short extension of the tubular shaft from the connecting rod cap.

The lubrication throughout is by pressure to the main bearings rather than by the rough system earlier in vogue in Knight motors. With the pressure system their is a flow in proportion to motor speed from 15 to 60 pounds pressure, the latter mark representing the high mark of pressure. The high-speed, high-efficiency motor has a three-part electric system including an Eisemann magneto constituting the only ignition system, a Gray and Davis cranking motor and also a Gray and Davis lighting generator.

The chassis possesses not a few improvements in spite of its price. First comes the use of spiral bevels in the rear axle, and also the use of a pressed steel axle housing taking the place of the forging type. The service brake is moved from the rear wheels to back of the gearbox; cantilever rear springs are introduced and the gasoline tank is placed in the cowl.

Besides being manufactured as a touring car it is marketed as a cabriolet and also a limousine.

Stearns is listing two other models, one known as the big four, 4.25 by 5.5 cylinders, and the other the six, 4.25 by 5.75. These are continued practically as during last year.—F. B. Stearns Co., Cleveland, O.

Stevens-Duryea Increases Bore

A 1-16-inch increase in bore in the larger motor, a shift from right to left drive and the fitting of electric starting and lighting as stock equipment are the three changes in Stevens-Duryea cars. While the roadster and touring cars are made under the same model number, they are really two different chasses, as the wheelbase for the roadster is 131 inches and for the touring car is 138 inches, the same as for 1914.

The feature of the new line is the roadster with a 4.325 by 5.5 power plant. Besides the novel adaptation of the streamline effect, a sloping deck has been provided which incloses a compartment for carrying two spare tires mounted on their rims, or one wire wheel mounted and an extra tire. When the top is down it disappears completely inside the body and it is supported by mechanical means by neat rigid joints which cause it always to follow a certain path when folding into and being withdrawn from the body. It is self-supporting and when up requires no braces, being rigidly fastened to the windshield support. When the top is folded, the concealing compartment is completely covered by the upholstery and when up the opening is also covered.

Except for the change in bore, the power plant for the touring cars remains the same. It is 4 7-16 by 5.5 suspended at three points. Like other Stevens cars this has a disk clutch, progressive three-speed gearset, floating axle and 37 by 4.5 tires.

A new type of auxiliary seat is used in the seven-passenger touring cars. Each seat has one upholstered arm on the inner side and the upholstered arm rail provides the rest on that side. The construction allows for folding backward and sidewise against the side of the tonneau, or it can be tipped forward in front of the entrance allowing plenty of room in the tonneau and concealing the extra seats from view An addition to the line is made in the form of a seven-passenger landaulet on a 139-inch wheelbase chassis.—Stevens-Duryea Co., Chicopee Falls, Mass.

Studebaker Alters Manifold

The two 1914 Studebaker chasses are continued with the same elemental features of design, but many alterations have been made, with the result that the cars are larger, although selling at $65 less for the four and $190 less for the six, making the present prices $1,385 for the five-passenger car and $1,450 for the seven-passenger six.

In both motors an increase of 15 per cent. has been made possible in the maximum power by reducing the weights of the reciprocating parts and altering the manifold design. Four ounces have been cut from the piston assembly and although the valve sizes remain the same, greater efficiency has been obtained by increasing the port sizes. The lubrication system has been maintained, but the scoop has been changed in shape and the splash troughs altered to give greater oil economy.

While the Schebler Model R carbureter is used this year, a water jacket and a means of pre-heating the intake gases from the exhaust are also included. In the four the carbureter bolts against the integral cylinder casting without any exterior intake manifold.

The same clutch has been maintained, but the leverage on the operating members on the six is altered to give an easier throw. Instead of the exterior flange connected with the wheel on the rear axle drive shaft there is now a tapered-fitting connection with the driving flange and in place of the flat plate the wheel now carries a hub cap.

By improvements in the body work and equipment much weight has been cut from these models. This has been effected by substituting pressed steel for wood and by the use of a new top. The instrument board is now a stamping and is free from the instruments. Side lamps are discontinued and the bodies are full molded stream effects.—Studebaker Corp., Detroit, Mich.

Stutz Has New Small Four

Two new Stutz cars have appeared for the 1915 season. One is a four-cylinder roadster on a smaller chassis than any yet put out by this concern and the other is a four-passenger speed body mounted on the same chassis as the roadster which has been marketed during the past year. This brings the line to ten cars, six fours and four sixes. Of the four-cylinder models the touring and sedan have a wheelbase of 130 inches and sell respectively at $2,275 and $3,675; the Bulldog roadster and Bearcat have a wheelbase of 120 inches and are listed respectively at $2,250 and $2,000.

The H. C. S. four, which is a new model and lists at $1,475, has a wheelbase of only 108 inches. Of the four sixes the touring and sedan, which have a wheelbase of 130 inches, cost respectively $2,400 and $3,800, while the roadster and Bearcat, which both have a wheelbase of 120 inches, are listed at $2,125 each.

The smaller car is a typical Stutz design except that an L-head motor is used, whereas former motors have all been T-heads. Another departure is the casting of the cylinders in blocks instead of pairs. The use of block cylinders and the connection of the forward end of the torque tube to the clutch housing instead of to a cross frame member has rendered possible a wheelbase of 108 inches, whereas the larger roadster has 120 inches.

The new four-passenger speedster is styled the Bulldog. It is mounted on a chassis of 120-inch wheelbase, this being the same chassis in every particular as that manufactured for the 1914 season.

The characteristics of Stutz design which are common to all the cars are the leather-faced cone clutch and the Stutz rear system with its three-speed gearbox mounted just forward of the differential housing in unit with the axle. Wire wheels are furnished at $100 additional and a wide range of body colors is optional.—Stutz Motor Car Co., Indianapolis, Ind.

Touraine Has a Six

Two Touraine cars, one a touring and the other a limousine, both of seven-passenger capacity are put out on the 134-inch wheelbase. The six-cylinder power plant has its 4 by 5.5 cylinders cast in threes. They are of T-head shape. The maker's rating of this motor is 61 horsepower at 2,220 r.p.m. The intake valves are located on the right and the exhaust valves on the left. Both camshafts are driven by spiral gears. The lubricating system is a circulating splash operated by a gear pump and the water cooling system has a centrifugal pump which forces the water through a honeycomb radiator.

For ignition a Bosch dual system is provided. The gasoline system is a pressure feed with the gasoline tank swung on the rear. The capacity of the tank is 23 gallons, and is used in connection with a 1.5-inch Zenith carbureter. Starting and lighting is by the Westinghouse 6-volt system with single wiring. The storage battery is a 150-ampere-hour Exide.

The clutch is a multiple disk carried in the flywheel having steel against raybestos friction surfaces. The gearbox provides four speeds and the rear axle is a floating design with the propulsion taken through the torsion tubes. Control is in the center with the steering wheel on the left. Full equipment is sold with the car, the tires being 34 by 4.5 with Q. D. demountable rims.—Touraine Motor Car Co., Philadelphia, Pa.

Trumbull Drops Friction Drive

The most radical change in the Trumbull car is in the transmission. The friction and chain drive has been eliminated, substituting in its place a selective, sliding gearset having three speeds. This is in unit with the differential on the semi-floating rear axle. A cone clutch is also used in connection with center control and the car has been equipped with both internal and external brakes operating on the rear hubs. The motor has been remodeled to some extent, principally in the shortening of the intake manifold which has resulted in the raising of the carbureter. A newly designed camshaft with cams which have been laid out along the line of quietness are also innovations.

The Trumbull is a miniature automobile. It is built along standard lines and has all the up-to-date equipment and luxuries of larger cars except the size. The wheelbase is 80 inches and the tread 44 inches. It is claimed that a fuel consumption of 35 miles per gallon of gasoline can be obtained with this little car. It is made in two styles for passengers, that is, a roadster and a coupé. Electric lighting and starting is extra but all the ordinary equipment is standard.

The four-cylinder motor has its 2.875 by 4 cylinders cast in a single block. It is lubricated by a combination pressure and splash system in which a pump delivers oil to all the main bearings and timing gears and the rest of the motor is lubricated by the splash. The two-passenger body which is regularly fitted is of the sociable roadster-type having the seat continuous without subdivision between the driver and passenger.—Trumbull Motor Car Co., Bridgeport, Conn.

Twombly Has Narrow Tread

Two-passenger bodies, a town car which serves as a taxicab and a roadster of two-passenger capacity are mounted by the Twombly company on their 100-inch wheelbase chassis with 44-inch tread.

The power plant is a four-cylinder 3.125 by 4 with L-head cylinders cast in a single block. The cylinder heads are removable which is unusual in the L-head type of construction. Both intake and exhaust valves are on the left and are driven from a single camshaft through a helical timing gearset. The intake and exhaust manifolds are cast together and are unjacketed. The motor is supported at three points.

Cooling is effected by a thermo-syphon system, lubrication by circulating splash and ignition by the Splitdorf single high tension system with hand control. The carbureter is optional, being either a Holly or Zephyr 1-inch, fed by gravity from the 8-gallon gasoline tank located in the cowl.

A cone clutch transmits the drive to a three-speed selective gearset located on the rear axle. From this point the transmission consists of a worm beneath the wheel mounted just to the rear of the gearbox and a semi-floating rear axle. The wheels are of wire and are undemountable. The tires are 30 by 3.5 and the rear spring is a compound cantilever. This spring, contrary to general light car practice, does not transmit the drive as this is taken through a torsion tube. Two sets of brakes are fitted, both on the rear wheels. The bodies though small, as is natural with the short wheelbase and narrow tread, are fitted with up-to-date equipment and deep upholstery.—Twombly Motors Co., New York City.

Velie Adds a Six

A new six named the Biltwel model at $1,595, is the leader of the Velie line. Besides this car two of last season's models, a four and a six, are continued. The six sells for $2,015 instead of $2,350 and the four at $1,750 instead of $2,000. Better bodies are used on these two cars, but no mechanical changes have been made.

The new six incorporates among its noteworthy features a spiral-bevel rear axle, Hotchkiss drive, Atwater Kent ignition with automatic spark advance and Stewart vacuum feed. The motor, a Continental 3 1-2 by 5, forms a unit power plant with a cone clutch and a four-speed gearset. The chassis frame has an unusual taper, the distance between front spring centers being 27 1-4 inches, allowing a very short turning radius. The equipment includes Gray & Davis cranking and lighting, power tire pump, auxiliary emergency battery for ignition, double headlights, inspection lamp, etc.

The four has a Velie-made motor 4 5-8 by 5 1-4 and two of the features are the transverse drive of the magneto, and the feed from the carbureter through a pipe passing over the cylinders to the other side of the motor. The drive system includes a disk clutch, four-speed gearset and Timken floating axle. The larger six is Continental equipped, the cylinders being 3 3-4 by 5 1-4, and in general design is the same as the new six.—Velie Motor Vehicle Co., Moline, Ill.

Vixen Has Friction Drive

A small 36-inch tread vehicle with a 106-inch wheelbase and fitted with a three-passenger tandem-seating body is being marketed by the Davis Co., under the name of the Vixen. It is fitted with a four-cylinder, block motor, 2 3-4 by 4, using Atwater Kent ignition and thermo-syphon cooling. The drive incorporates a friction set located under the rear seat there being one friction driving wheel for each rear wheel. The disks are fiber against iron and the final propulsion is by side chains to the wheels. The latter are wire 28 by 3.—Davis Mfg. Co., Milwaukee, Wis.

Vulcan a New Block Four

The Vulcan company has brought out a new car for this season. It is fitted with a Buda four-cylinder 3.5 by 5.125 power plant, multiple disk clutch, Fuller three-speed gearbox, three-quarter floating rear axle and is mounted on a wheelbase of 120 inches. This chassis is provided with a five-passenger touring body of streamline design.

The L-head cylinders are cast in a block and are provided with integral water jackets which are so baffled that the water is discharged directly beneath the valves and circulates entirely around these cylinders. The top of the cylinders is provided with a cover which can be removed allowing access to the water jackets. The base flange of the cylinder casting is continued horizontally to form a housing for the valve lifter guides.

The crankshaft is carried on three main bearings and is of open-hearth steel having a tensile strength of 120,000 pounds to the square inch and an elastic limit of 85,000 pounds to the square inch. The bearings are lined with die cast nickel babbitt and the camshaft bearings which are also three in number are lined with phosphor bronze.

A combination splash and pressure system takes care of the oiling. A gear pump takes the oil from the lower half of the crankcase to the tops of the main bearings and the lubricant flows from these to the splash trough.

In the clutch there are eight plates lined with raybestos. These deliver the power to the three-speed gearbox which is mounted on imported ball bearings transmitting the power to a Salisbury three-quarter floating rear axle. The springs are cantilever design 48 inches in length. Steering is by worm and wheel.

The body lines are continuous, following the dictates of streamline fashion, and provide 24.5 inches leg room in the rear and 33 inches leg room in the front. The fenders are crowned and made from 22-gauge fender steel.—Vulcan Mfg. Co., Painesville, O.

Westcott a Four and Six

Two cars, a four and a six, of the same principle specifications throughout except in regard to the number of cylinders and the rear axle, make up the Westcott line. Both motors are L-head blocks with 3.5 by 5-inch cylinders giving S. A. E. horsepower rating of 19.6 and 29.4 for the four and six respectively. The valves of the motors are on the left, both operated by camshafts with the cams cut integrally. The camshafts are driven by helical gears and the valve adjustments are accessible by means of removable cover plates.

Pump water circulation is used for cooling, and oiling is by splash with the lubricant circulated by means of a plunger pump driven off the camshaft. Delco dual ignition starting and lighting is standard equipment on both models. The ignition system is provided with automatic spark advance.

On both models the clutch housings and gearboxes are part of the unit power plant suspended at three points. The power is delivered by cone clutches to three-speed selective gearboxes. The final drive is accomplished by bevel gears. The thrust of propulsion is taken through the springs. The rear axle on the model O which is the four-cylinder car is a three-quarter floating while that on the model U, the six, is a floating design. A difference in final gear reduction will be noted on the two cars. That of the four is 4 to 1 and on the U it is 3.77 to 1. The wheelbases are respectively 113 and 125 inches for the four and six. The smaller car uses 33 by 4 tires and the six 35 by 4.5. Both cars have wood wheels and left drive with center control. The springing differs materially, however, as cantilevers are used on the six and three-quarter elliptics on the four.—Westcott Motor Car Co., Richmond, Ind.

White Makes Six to Order

Listing only two four-cylinder models and building the six to custom order is one example of the practical discontinuance of the six. This is the White policy, the fours being generally improved, fitted with an entire line of new bodies and slightly increased in price. One dominant factor in the new Whites is the lower bodies, the frames now being but 25 inches from the ground yet allowing for a clearance of 10 inches under the apron. In the large four this lowering is accomplished first by underslinging the three-quarter rear spring, second by dropping the frame side members and lastly by dropping the front axle.

The chassis has been altered in many respects notwithstanding the continuation of block type cylinders with integral manifolds, four-speed gearsets and disk clutches. The Entz motor generator, heretofore under the hood, is now located at the right rear of the chassis, approximately under the tonneau floor, and in this new position is driven by a forward shaft and sprocket and silent chain from the flywheel. The new position is more accessible and the drive is not through the timing gears as formerly. A great improvement has been made in the wiring, all of which is brought to a junction box on the front of the dash immediately over the steering column.

Gasoline feed is now by the Stewart vacuum system, which permits the carbureter being carried much higher, being directly bolted to the side of the casting, and also allows of a rear gasoline tank on all models. All motor and lighting controls are mounted on the forward side of the steering column below the wheel, the control box being a cylinder shape placed transversely on the column. A new form of clutch brake is intended to stop spinning in gearshifting; and there is now an equalizer in the service brake as well as in the emergency one. All lights take 21-volt bulbs. The oil reservoir is removed from the side of the motor and placed on the forward side of the dash; Silverton cord tires are stock.

Bodies are new streamline creations with a flaring hood which leads into a heavy cowl with a backward curve directing the eye to the seat line. Back of the front seat is a center cowl, which aids in carrying out the streamline design. The bodies are widest in rear of the front seats. Auxiliary tonneau seats are sunk 2.75 inches into the floor so that the passengers do not sit higher than those on the rear seats. Crowned fenders are used; the windshield is very low and tilts back; upholstery is tufted vertically rather than in diamond pattern; and a one-man top is standard. Compartments in rear of the front seat are fitted in some models.—White Company, Cleveland, O.

Willys-Knight Heavier Axle Housing

The new Willys-Knight, model K-19, is practically the same mechanically as its predecessor, model K-17, but it has a new streamline body and sells for $275 less, or $2,475. The body changes are radical, the hood being sloped and a rounded cowl uniting it with the body. The older car had a straight hood, and there was a decided break between bonnet and body. A slight change is found in the floating axle, which has a new design of housing stronger and lighter than the old. The gearbox is somewhat different in design.

The motor, a Knight type with sliding-sleeve valves, has cylinders 4 by 5 1-2 cast in pairs and with removable heads. The engine uses a five-bearing crankshaft, and is a standard Knight design.

Ignition is by a high-tension magneto which is independent of the cranking and lighting system, the latter being of the combination type with the motor-generator in the flywheel. Force feed oiling is used, and cooling is by a centrifugal pump.

The rear axle, with its new and lighter housing, is still a worm drive type, with the worm carried under the worm wheel, and running continually in a bath of oil. The ratio is 4.83 to 1. Drive comes back to it through a cone clutch and open drive shaft with two universals. The four-speed gearset is located in the center of the chassis.

The rear spring suspension is the Lanchester cantilever form, with these springs measuring 52 by 2 1-4 inches. They attach at two points outside the side frame rails and at their rear end to the axle tubes.

Center control with left steering are employed. Tires are 36 by 4 1-2 on demountable rims.

The standard body finish is a dark blue with ivory striping, and a feature of the front seat is the adjustable cushion to accommodate the driver in reaching the control pedals.—Willys-Overland Co., Elyria, O.

Winton Announces Smaller Six

Winton has entered the lists of those who are making two models, having just announced an additional car known as 21-A which is a smaller six than the model 21. In general design the new car is similar to the larger model but is smaller throughout. While the model 21 has a 4.5 by 5.5 power plant the 21-A dimensions are 3.625 by 5.25. The wheelbases of the two cars are respectively 130 and 128 inches and the tire sizes 37 by 5 and 36 by 4.5.

The only change made in the large car is in the refinement of the bodies and the increased radiator size. The small car is a new job throughout. Like its older brother the power plant has its six cylinders cast in an L-head with the valves on the left. The valve action is inclosed and the crankcase is extended back to include the flywheel. In the former model the flywheel was not inclosed.

The valves are tungsten steel on the exhaust side and carbon steel with nickel steel heads on the intake. The valve springs, plungers and adjustment nuts are covered by steel plates which are detachable by removing hand screws.

The crankshaft is of chrome vanadium steel carried on four plain bearings lined with white brass. All the bearings are carried in the upper half of the crankcase. A point in which the new model differs from the old is in the mounting of the carbureter and other auxiliaries. The carbureter is carried quite high and is bolted by means of a short elbow against the balanced intake manifold. The carbureter and magneto on the new model in connection with the generator and water pump are all on one side of the motor, leaving the left side absolutely clear except for the Bijur cranking motor which is on a bracket in connection with the left rear foot of the crankcase.

Pressure feed lubrication is used and ignition is by the Bosch dual system. The cooling water is circulated by gear-driven centrifugal pump which forces the water through jackets which are lined with an anti-corroding surface. The radiator is a honeycomb and it is bolted to the drop frame. Lighting and starting is by the Bijur two-unit system.

The drive is transmitted through an eleven-disk dry plate clutch, a four-speed gearbox and a driveshaft which has a universal joint at each end. Spiral bevel drive is used and the rear axle is floating. The Winton company offers five gear reductions running from 3 1-16 to 1 to 4 1-12 to 1. All types of body are mounted on the new car.—Winton Motor Car Co., Cleveland, Ohio.

Zimmerman Continues Its Six

The six-cylinder car rated at 55 horsepower which was marketed by the Zimmerman company for the 1914 season will be continued for 1915. The two-cylinder models which were known as D & E and which could be secured last season have now been discontinued in line with the policy of American manufacturers to eliminate the two-cylinder car. Zimmerman last season was among the few that remained for 1914 who continued to market the two-cylinder car. This year there are but .5 per cent. who still continue the two-cylinder policy.

The six-cylinder car is an up-to-date design in every particular. The body work has been improved this season and the side lamps have been eliminated, leaving the running lights contained in the headlamps. The dimensions of the motor are the same as for 1914, being 4 by 5, with L-head cylinders cast in pairs. The chassis is provided with a disk-in-oil clutch and three-speed gearset. Ignition is by the Remy dual system and electric starting is used. For 1914 Zimmerman offered an option of compressed air or electric starting. The car is sold fully equipped and is mounted on a 132-inch wheelbase.—Zimmerman Mfg. Co., Auburn, Ind.

Events Scheduled for Show Week

The Show

Fifteenth Annual National Automobile Show, Grand Central Palace, January 2-9, Beginning at 2 p.m. on Saturday, January 2. Other Days Show Opens at 10 a.m. and Closes at 10.30 p.m. Admission 50 Cents. Except Society Day, Wednesday, January 6, When It Is $1.

No Commercial Cars Shown—Special Information Bureau for Commercial Vehicle Manufacturers.

Motor Truck Club of America's Offices Will Be Open Evenings for Convenience of Truck Representatives. The Club Will Make Arrangements for the Rental of Additional Office Space at 1790 Broadway, for Use of Visiting Truck Manufacturers and in Conjunction with the Activity of the National Automobile Chamber of Commerce Along Similar Lines.

Exhibitors Will Be Obliged to Get Their Displays in Building and Completely in Place Before 12.30 p.m. of Opening Day. After That Hour No Goods Will Be Admitted.

Social and Business

Jan. 4—Chalmers Motor Co.—Dealers' Meeting at Healy's, 66th street and Columbus avenue.

Jan. 4—Motor Dealers' Contest Assn.—Board of Directors' Meeting, 222 West 59th street, 1 p.m.

Jan. 5—National Automobile Chamber of Commerce—Patents Committee Meeting, 7 East 42nd street, 3 p. m.

Jan. 5—Studebaker Corp.—Dealers' Meeting, Manhattan Hotel.

Jan. 5—Society Automobile Engineers—Meeting Standards Committee, Society Headquarters, 1790 Broadway.

Jan. 5—National Automobile Chamber of Commerce—Banquet at Waldorf-Astoria, 7 p.m.

Jan. 6—Motor and Accessory Manufacturers, 33 West 42nd street.
Executive Committee Meeting, 9.30 a.m.
Finance Committee Meeting, 10 a.m.
Board of Directors' Meeting, 11 a.m.
Twelfth Annual Meeting, Waldorf-Astoria, 3 p.m.
Annual Banquet, Waldorf-Astoria, 7.30 p.m.

Jan. 7—Motor and Accessory Manufacturers—Board of Directors' Meeting at 33 West 42nd street, 2.30 p.m.

Jan. 6—National Automobile Chamber of Commerce Meeting, 7 East 42nd street, 10 a.m.

Jan. 6—Cycle Parts and Accessories Assn.—Annual Meeting, Hotel Astor, 10 p.m.

Jan. 6.—Briggs-Detroiter Co.—Meeting of Eastern Dealers, Vanderbilt Hotel.

Jan. 7—Briggs-Detroiter Co.—Meeting of District Sales Managers, Vanderbilt Hotel.

Jan. 7—Franklin Automobile Co.—Dealers' Get-together Dinner, McAlpin Hotel, evening.

Jan. 7—Chas. E. Riess & Co.—Dinner at Vanderbilt Hotel.

Jan. 7—Willys-Overland Co.—Banquet at Biltmore Hotel, evening.

Jan. 7—Paige-Detroit Motor Car Co.—Dealers' Dinner at Riesenweber's, 58th street and 8th avenue, 7 p.m.

Jan. 7—Saxon Motor Co.—Dealers' Luncheon, Knickerbocker Hotel, 1 p.m.

Jan. 7—A. J. Picard & Co.—Dealers' Dinner at Cafe Des Beaux Arts; Trip to General Electric Plant, Lynn, Mass., by special train.

Jan. 9—Chandler Motor Car Co.—Dealers' Dinner at Manhattan Hotel, 11 p.m.

Jan. 9—American Automobile Assn.—Executive Board Meeting, 437 Fifth avenue, 10 a.m.

S. A. E. Program

Tuesday, January 5, at 1790 Broadway

Standards Committee, 9 a.m.
Governing Committee of the Sections, 8 p.m.
Council Meeting, 8 p.m.

Wednesday, January 6, at Engineering Societies Bldg.

Business Session, 10 a.m.

President's Address.
Treasurer's Report.
Report of Tellers of Election of Officers.
Report of Membership Committee.
New Business.
Report of Ball and Roller Bearings Division—F. G. Hughes, Acting Chairman.
Report of Carbureter Fittings Division—J. J. Aull, Acting Chairman.

Professional Session, 1 p.m.

Automobile Bodies—H. J. Hayes.
Report of Commercial Car Wheels Division—Wm. P. Kennedy, Chairman.
Report of Electric Vehicle Division—A. J. Slade, Chairman.

Continuation of Professional Session, 8 p.m.

Pros and Cons of Correct Tire Inflation—C. B. Whittelsey.
Report of Pleasure Car Wheels Division—Henry Souther, Chairman.
Wire Wheels versus Wood Wheels—R. B. Mudge.
Wire Wheels versus Wood Wheels—Geo. W. Houk.
Report of Lock Washer Division—C. E. Davis, Acting Chairman.
Report of Miscellaneous Division—J. G. Utz, Chairman.

Thursday, January 7, at Engineering Societies Bldg.

10 a.m.

Report of Electrical Equipment Division—A. L. Riker, Chairman.
Railway Gasoline Locomotives—A. B. Ehle.
An Eight-Cylinder Motor—H. G. Chatain.
Report of Research Division—David L. Gallup, Chairman.
Universal Joint Efficiency—C. W. Spicer.

1 p.m.

Malleable Iron Castings—Dr. Richard Moldenke.
Report of Frame Sections Division—J. G. Perrin, Chairman.
Report of Iron and Steel Division—Henry Souther, Chairman.
Nomenclature of Car Parts.
Allowances for Piston Fits—E. W. Weaver.
Worm Gearing by a New Process—C. T. Myers.
Discussion of Time and Place of 1915 Summer Meeting.

8 p.m.

Automobile Engineering Curricula—Prof. W. T. Fishleigh.
Motor Car Testing—A. B. Browne and E. H. Lockwood.
Warning Signals—Alden L. McMurtry.
Report of Springs Division—C. W. McKinley, Chairman.
Cantilever Springs—J. G. Utz.
Report of Standards Exchange Division—K. W. Zimmerschied, Chairman.
The European Situation as Affecting America—A. Ludlow Clayden.

Informal Dinners at Bustanoby's Restaurant, 110 West 39th Street

Wednesday, January 6, 6.30 p.m. Thursday, January 7, 6.30 p.m.

A Directory of Automobile Makers

HEREWITH appears a tabulation of the 1915 lines of 117 automobile manufacturing companies, an analysis of which brings out the concentration of production gradually being adopted. That is, of the 117 companies, fifty-eight are making one chassis only; forty are building two chassis; fifteen have three chassis; and only two are manufacturing four and five chassis.

There are two eight-cylinder models listed for 1915, one maker dropping all other models and the other continuing a four. There are sixty-eight builders of sixes, thirty-one of whom make this type only. Eighty-four companies are listed as manufacturing four-cylinder cars, forty-six of them making fours only. Thirty-six concerns are including both four- and six-cylinder chassis in their lines. There is one two-cylinder.

Of the six-cylinder car builders, forty-five have one model only, nineteen have two, three have three chassis and only

*1 Eight-cylinder chassis. **1 Two-cylinder chassis. ***1 Center drive. O—Optional.

one has four. Among the four-cylinder makers, sixty-eight have but one chassis model, fourteen have two and two companies have three.

Eighteen concerns still make right-drive models, four of them having two models with this type of steering, while two have three chassis and one five. The remaining eleven have one chassis each with right drive. Left drive, on the other hand, is used by ninety-eight makers. Four concerns build cars with each type of drive. There is one car with center drive and with eight companies right or left drive is optional.

Three firms use worm drive and fourteen fit wire wheels, which are optional with seven. Electric crankers are used by 106, air by two, mechanical by one; with two the system is optional, and two have none.

As regards bodies, there are ninety-two companies including two-passenger roadsters in their lines, twenty having two models of this type, nine having three and one each four and five. Fifteen of the companies make four-passenger touring cars, five having two models, one three and the rest but one. Eighty-five build five-passenger types, twenty-six making two models, seven listing three, one five and the other fifty-one making but one. Twenty firms include six passenger bodies. Seventeen are building coupés and thirty-nine are listing large inclosed models.

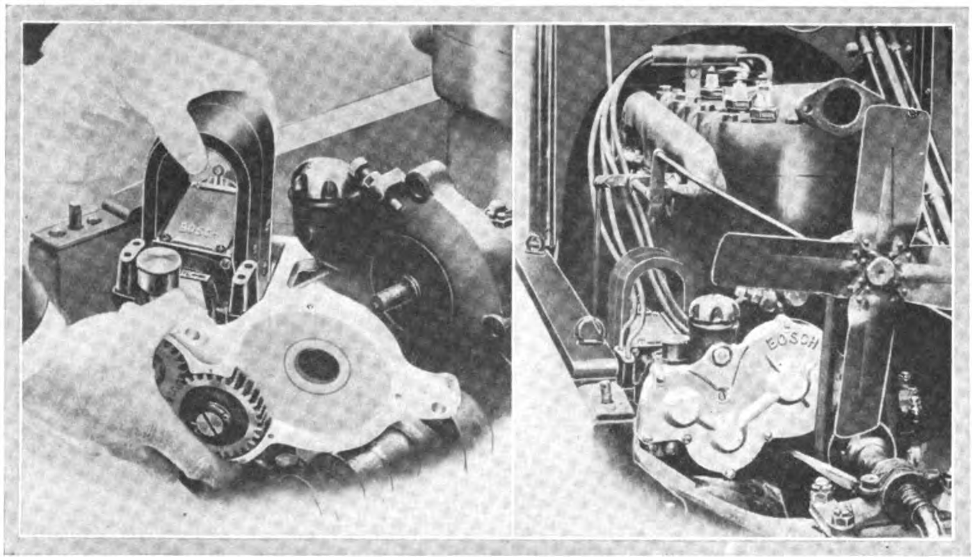
Gear-Driven Bosch Magneto for Ford

NU4 Magneto Used—Placed on Right—Price Lower



Left—Bosch outfit in process of installation on Ford. Right—Bosch outfit in place

A NEW magneto attachment for Ford cars has been brought out by the Bosch Magneto Co., 223 West Forty-sixth street, New York City. It is gear driven, is placed on the right side, incorporates an NU4 magneto, and the price is $48 in contrast with the older Ford ignition system in which chain drive is used, the magneto is situated on the left side, the instrument is a DU4 and the price is $58. The development of the new outfit was in response to a demand for a gear-driven instrument which might be placed on the right side of the motor.

The magneto which is supplied with the attachment was described in the September 24, 1914, issue of THE AUTOMOBILE and is the same as that fitted to the new model 80 Overland cars. It differs from the usual Bosch high-tension machine, in that it has no distributer, properly speaking, the high and low-tension windings being entirely insulated from each other. The breaker box mechanism is similar to other Bosch machines, however. The two ends of the secondary winding are connected to the two metal segments located on the double slip ring mounted on the armature.

Bearing against the double slip ring are two pairs of brushes, each brush being connected to a spark plug wire. As the armature shaft rotates the segments form a contact in turn with each of the four brushes sending the spark to each plug in turn.

In making the installation the first procedure is to drain the cooling system and remove the radiator. Then the timer case is discarded. The driving gear is attached to the crankshaft and the new timing gearcase which carries the magneto is put in place.

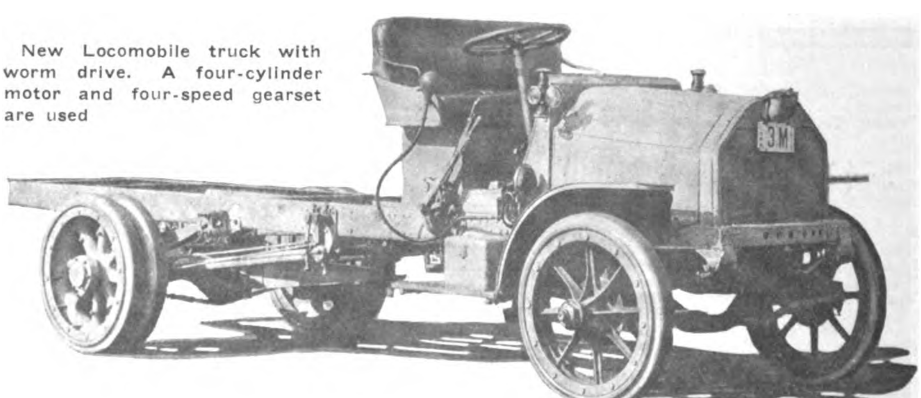
Worm Drive on New Locomobile 3 and 4-Tonners

BRIDGEPORT, CONN., Dec. 29—The Locomobile Co., of this city, has added to its line of chain-driven trucks two new models, a 3-ton and a 4-ton, both worm-driven types, these models marking the entry of this company into the worm drive field. Both models are practically alike in every respect excepting that in the 4-ton heavier rear tires and heavier rear springs are used. The designs have been on the road undergoing tests for practically 2 years and at the present time the company is working full capacity on a production of 1,200 for next year. The first lot of 500 is at present going through the factory, and by March 1 it is estimated that production will be thirty to thirty-five vehicles a week.

Both of these new worm-driven types differ from the previous 5 and 6-ton chain-driven types in that the worm drive models have the motor under a hood with the driver's seat in rear, as compared with the motor being located under the seat in the larger chain-driven types. Throughout the new models the same grade of material is used as employed in the Locomobile passenger cars, nickel and chrome nickel steel finding places in many parts of the trucks, including alloy steel springs.

Both models use a four-cylinder motor 4 1-4 by 6, and drive through a four-speed gearset with 1 1-4 inch gears.

The new axle design has a housing made up of steel casting housing the differential and worm and worm wheel. The worm is mounted above the wheel and is a quadruple, straight-thread type. On each model, two reductions are given, one 8 3-4 to 1, the other 10 to 1, and the engine governor is set so that using the 8 3-4 to 1 ratio the truck speed is 14 miles. There are two wheelbase lengths, 150 and 186 inches. On the 3-ton tires are 36 by 5 with rear duals. On the 4-ton fronts are 36 by 5 and the rears 36 by 6 duals.



New Locomobile truck with worm drive. A four-cylinder motor and four-speed gearset are used

Friction Disks in New Hartford Absorber

Frictional Resistance Proportional to the Severity of the Shock—Adjustable to Different Cars

THE distinguishing feature of the new shock absorber that has just been put on the market by the Hartford Suspension Co., Jersey City, N. J., is that it automatically proportions its own frictional resistance to the severity of the road shocks. In one respect it resembles a multiple-disk clutch in that the friction element consists of five steel disks and six brass disks, alternately placed, the whole being held under spring compression in a housing which carries the two arms which connect with the frame and axle of the car. One of these arms is fastened to the brass disks and the other to the steel ones.

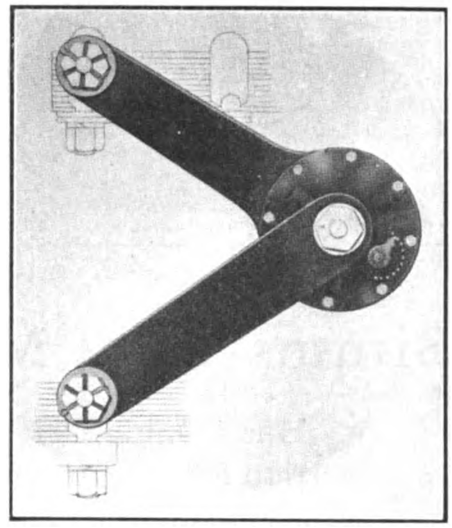
The progressive action, which is the feature of the new device, is obtained by so designing the device that a small movement causes only two brass disks and a steel disk in between to offer frictional resistance. A further movement brings in two more disks, and so on until the maximum movement brings all disks into play.

Referring to the accompanying illustration showing the shock absorber disassembled, it will be noted that the brass disks are bolted to the cover plates and the arm A.

The steel disks have internal lugs which engage corresponding flutes on the body of the center hub, the latter being rigidly attached to the arm, which is fastened to the car spring or axle, as the case may be.

However, the flutes on these disks are not all the same size, and this is how the progressive movement is obtained. There is only one steel disk that fits tight on the center hub. On the second steel disk the flutes are further apart and there is considerable play between the disk and the hub; on the next steel disk there is still more play, and so on, the fifth disk having the most play.

When the springs of the car are compressed only slightly, due to a minor road shock, the two arms of the shock absorber are brought closer together and this causes a partial revolution of the first steel disk between the brass ones on each side of it—the other steel disks are not brought into action because of the lost motion in the flutes. The friction due to the rotation of this steel disk between the two brass ones opposes the spring movement, absorbing the shock and preventing a quick rebound.

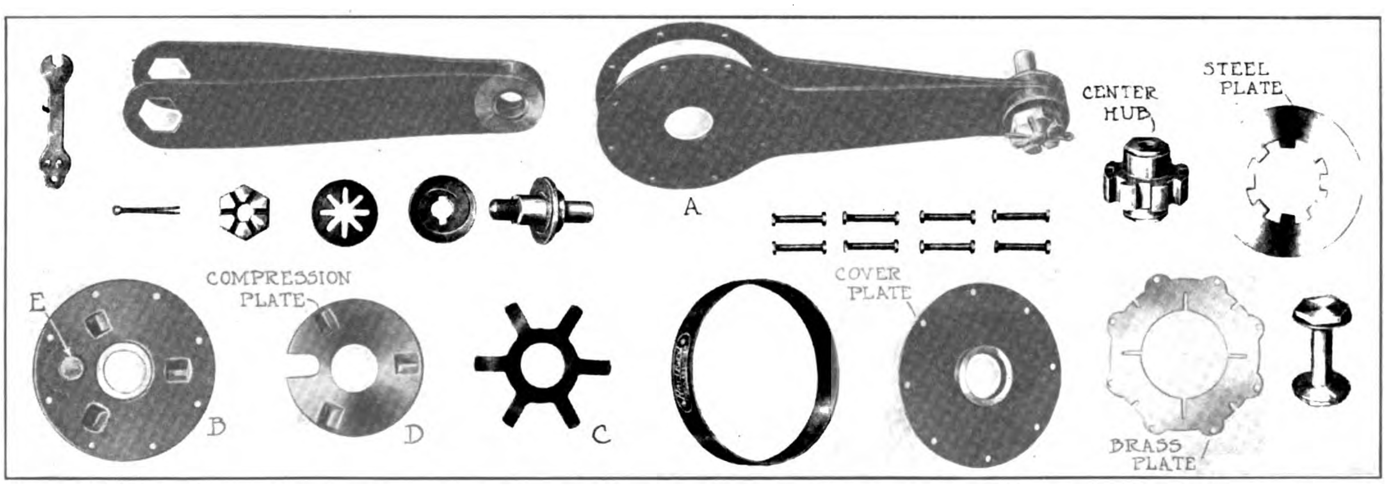


New Hartford shock absorber mounted on car

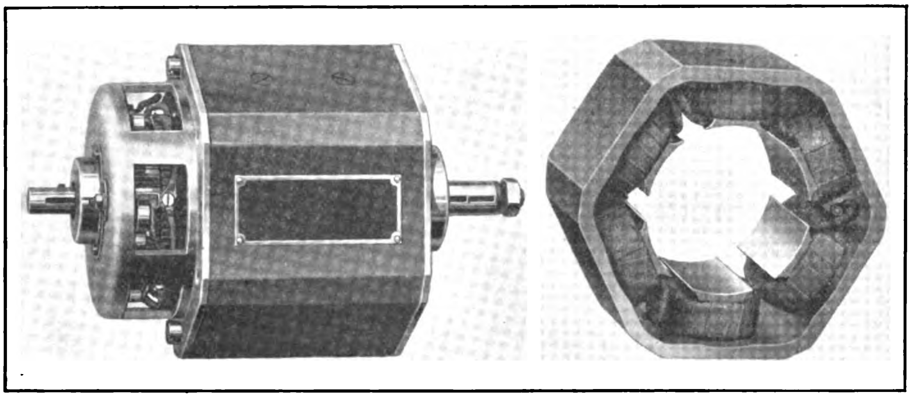
Under a heavier road shock, the first steel disk rotates between the brass ones on each side, but soon the movement is sufficient to take up the lost motion in the second steel disk and it rotates with the first one, thus there are now two steel disks and three brass ones in action. A shock which is still more severe will take up the lost motion in the third steel disk and then there will be three steel disks and four brass ones opposing their frictional resistance to the movement of the spring. Fourth and fifth disks operate similarly.

Progressively then with the increasing spring movements due to increasingly severe shocks the impact is taken up, first in three disks, then in five, then in seven, then in nine and finally in the full set, the frictional resistance automatically increasing with the magnitude of the spring movement as the varying clearances of the lugs on the steel disks are taken up by the flutes in the center hub. Progressively in the same way the rebound of the spring is opposed.

The frictional resistance between the disks may be adjusted to the peculiarities of the car or to meet the owner's preference. Between the cover plate B and the spring spider C is the compression plate D bearing on its exterior, three wedge-shaped elevations. On the interior of the cover plate B are three corresponding wedge-shaped depressions. The eccentric button E on the interior of B engages the slot seen in D. The adjusting wrench F fits over the indicator arm mounted on the stem of the eccentric E. By turning the eccentric the compression plate D is forced inward, thus compressing the spring and increasing the friction.



Hartford shock absorber showing different parts used in its makeup. Six brass disks are bolted to one arm and five steel ones are keyed to a hub attached to the other arm

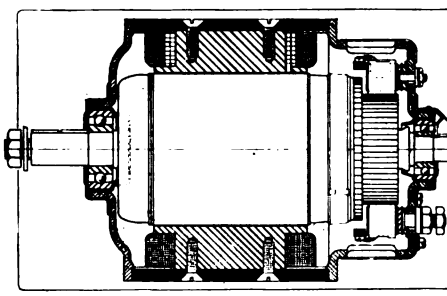


Left—Complete machine. Right—End covers removed showing six poles

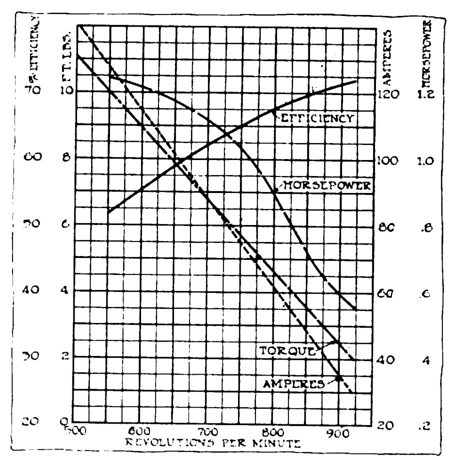
Simms-Huff Motor-Generator

Has Double Drive—Positive Connection for Starting and Belt for Lighting

A MOTOR-GENERATOR, known as the Simms-Huff, has been added to the line of the Simms Magneto Co., East Orange, N. J. The feature of the device is the use of a belt drive when the machine is operating as a generator, the slippage of the belt being used to adjust the output to the desired amount at any given speed. Voltage regulation is inherent and is obtained by opposing the series and shunt fields. Starter drive is optional. It may be through the flywheel or by chain to the crankshaft or through the timing gears. In any case an over-running clutch must be used. As a starting motor the device operates at 12 volts and as a generator at 6 volts. By the use of a 12-volt starting current the lock torque is stated to be 24 pounds although the complete instrument weighs but 30 pounds.



Pole and commutator construction



Performance curve showing efficiency, horsepower, torque and amperes plotted against revolutions per minute when the machine is operating as a motor

The features of the instrument include light weight, hexagonal shape to facilitate mounting, an unusual method of disposing of the armature windings and a unique type of brush holder which eliminates all but one wire. The unit is exceptionally compact yet accessibility has in no wise been sacrificed. All the mechanism that requires inspection: brushes, brush holders and commutator, may be exposed by the removal of a single metal casing which slips over the end.

In starting, all the cells in the battery are in series to give the required 12 volts but when the engine is running, the unit automatically becomes a generator and delivers 10 to 15 amperes to the battery at 6 volts pressure.

Series and Shunt Fields

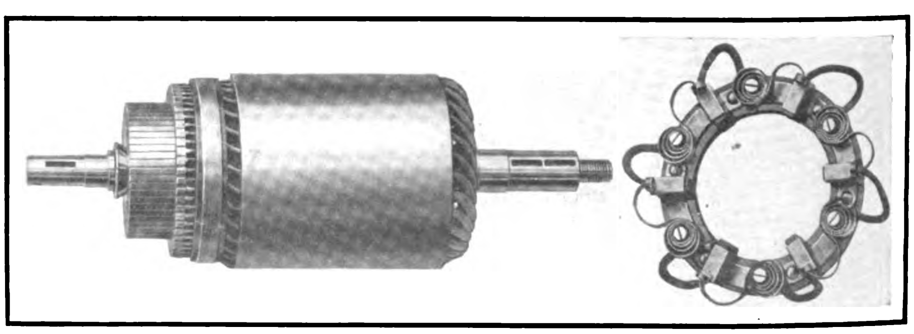
As previously noted, there are two windings, a series and a shunt, which add their magnetic strength when the machine is operating as a motor, but when the device operates as a generator the net field strength is the difference of the two fields and in this way the field strength is kept from rising with the speed, with the result that the voltage is maintained nearly constant. A charging rate of from 8 to 15 amperes at from 12 to 18 miles per hour may be obtained by simply varying the belt tension and allowing the armature to slip. If the ammeter registers less than 8 amperes at 12 miles per hour for instance it indicates that the belt should be tightened, a means for this process being provided in a slotted segment and set bolt on the fan support. It is pointed out that by this method of regulation the charging rate can be altered at will to correspond to changes in temperature and lighting load.

The starting switch is arranged to automatically make the necessary series connections at the battery for the starter and parallel connection for lighting. In addition there are two terminals which may be used for a battery circuit in the event of dual ignition being used.

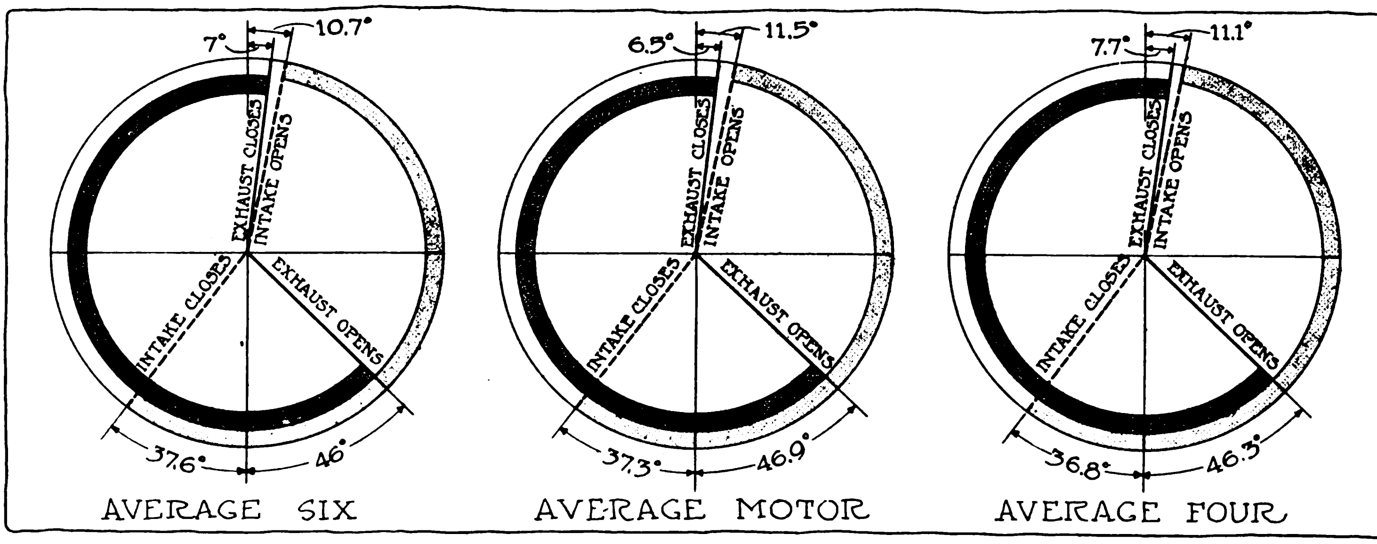
The cutout, which may be mounted on the dash, is of the usual reverse current relay type. It automatically connects the generator and battery when the charging current builds up to the proper strength. The brush holding mechanism is unusual in that all the wires with the exception of one have been eliminated by connecting each set of three brushes to a metallic ring, one of which is a permanent ground and the other, which is a single wire connection, going to the field winding. Thus six wires are done away with.

Holes Instead of Slots

The winding of the armature is another feature that is different from usual practice. Though it is of the drum wound type, the winding is passed through circular holes punched in the core laminations. The result is that the wires are thoroughly protected and cannot be thrown out by centrifugal force should the starting gear stick and cause the armature to rotate at excessive speed and additional surface is exposed to the action of the field. The system, which is at present used only by the Maxwell company, may be readily adapted to almost any other car.



Left—Armature showing how windings are passed through holes in the core instead of slots, thus giving a smooth exterior to the armature. Right—Simple brush construction



Left—Diagram of valve timing on the average six-cylinder motor. Center—Timing on the average motor, taking into consideration two-, four-, six- and eight-cylinder types. Right—Timing on the average four cylinder

Negative Lap Gains in Valve Timing

The Average Intake Remains Open Through 205.8 Degrees, While the Exhaust Is Open Through 233.4

VALVE timing has not under gone any radical revision since the models for 1914 were announced. Taking all the motors on the market and striking a general average of the timing the inlet valve would open at 11.5 degrees upper dead center and would close at 37.3 degrees past lower center. The exhaust valve would open at 46.9 degrees before lower center and would close at 6.5 degrees past upper center.

This average timing does not differ materially from the average timing for the 1914 motors when the intake opened at 11.2 degrees past upper center and closed at 35 degrees past lower center, and the exhaust valve opened at 50 degrees before lower center and closed at 9.3 degrees past upper center. A study of these two timings reveals that the intake on the 1915 motor opens at practically the same time as on the 1914 motor. There is a difference of .3 degree which, when considered in piston travel is so small as to be negligible. The inlet closes 2.3 degrees later. This is also a small difference and probably could not be detected on a testing dynamometer.

Exhaust Opens 3.1 Degrees Earlier

In exhaust valve timing practice the time of opening on the average motor is 3.1 degrees later on the 1915 motor than on the 1914. This is more significant as with the increase in the high-speed design it would be thought that there would be a trend in the opposite direction and that the designer would endeavor, in the light of the higher piston speeds, to let the gases out of the cylinder earlier, to be sure that the pressure in the cylinder would have fallen to atmospheric by the time that the piston reached the bottom of the stroke. The longer stroke is no doubt responsible.

Exhaust valve closing is earlier in 1915 motors than it was in 1914, by nearly 3 degrees. This is also a significant fact as the relation of the inlet opening to the exhaust closing, in other words the lap is considered the most important feature in laying out the valve timing. The negative valve lap has increased on the average motor from —1.9 degrees in 1914 to —5 degrees in 1915.

There are three conditions of valve lap used in timing practice: negative, zero and positive. The decided trend is towards the use of a negative lap, that is one in which the closing of the exhaust does not lap over the opening of the intake. In 1914, 66.6 per cent. of the motors had negative lap. For 1915, 69 per cent. are using the negative lap. Zero lap, in which the inlet valve opens at the same time that the exhaust valve closes was used on 11.9 per cent. in 1914, it is used on 19.3 per cent. in 1915. Positive lap where intake and exhaust valves remain open together during the year has fallen off from 21.5 per cent. to 11.7 per cent.

The three conditions of negative zero and positive lap in valve timing give rise to definite sets of conditions in the cylinder. With negative lap, which is the general condition, the exhaust valve closes an appreciable period before the inlet opens. This permits the piston to descend slightly on the suction stroke before the inlet valve opens, thus creating a vacuum in the combustion space. When the inlet valve opens the rush of gases into the cylinders is accentuated by the fact that they are entering a partial vacuum.

With zero lap there is no vacuum in the cylinder at the time of the inlet valve opening, theoretically speaking. The inlet gases are drawn directly by the piston which has generally started on its downward stroke, except in such cases where the position of zero lap is on upper dead center.

With positive lap, both exhaust and inlet are open together for the period of the lap. The theory of this timing arrangement is that the inertia of the exhaust gases passing through the exhaust port is sufficiently great to create a partial vacuum in the combustion space. This aids the intake in the same manner as the negative lap would do. Owing to the condition that the exhaust and inlet gases should not conflict in their direction with positive lap, it is generally used on T-head motors. The falling off in percentage of T-heads is doubtless in some degrees responsible for the falling off in the percentage of those using positive lap.

The motors using zero lap are Abbott, Buda, Cadillac eight, Case, Chalmers, King eight, Continental, Herschell-Spillman, Kline, Lexington, Lyons-Knight, McFarlan, Maxwell, Metz, National, Pratt, Premier, Saxon, Teetor and Vulcan. The point of inlet valve opening and exhaust valve closing on cars using the zero lap varies through a wide range. Cadillac, King and Case are examples of where makers have found it wise to open the inlet and close the exhaust on upper dead center. The latest timing for the zero lap is on the Saxon where the coinciding valve time falls at 12 degrees past upper center. The use of the upper dead center on the Cadillac is interesting as it is the first clue as to the timing requirements of an eight.

Those who still adhere to the positive lap are Auburn, Briscoe, Coey, Cunningham, Dorris, Franklin, Herff-Brooks, Locomobile, Paige, Simplex and Overland. It is interesting to note that three of these, Cunningham, Dorris and Franklin are overhead motors.

The greatest positive lap used on any car is in the Locomobile. This concern keeps both the exhaust and intake open during a period of 16 degrees and 27 minutes. Closely following this is Simplex which has an overlapping period of 16 degrees and 26 minutes. The smallest overlap is 5 degrees which is used on Briscoe, Dorris and Herff-Brooks motors.

The question as to whether the average timing for the four would vary much from that of the six can be answered in the negative. The timing diagrams at the head of page — bring out the small difference very clearly. On the six the inlet opens at 10.7 degrees past upper center and closes at 35.6 degrees past lower center. On the four it opens at 11.1 degrees before upper center and closes at 36.8 degrees past lower center. The difference of .4-degree on inlet opening and 1.2-degree on inlet closing would never be noticed in piston travel and would hardly make the difference of the thickness of a center-punch mark on the flywheel.

In exhaust valve practice the difference is also too small to be noticed. The exhaust on the average six opens at 46 degrees before lower center and on the average four is within .3 degree at 46.3. The difference in the points of exhaust closing is also less than a degree, being 7 degrees after top center on the six and 7.7 on the four.

1915—A 7-League Stride in Car Design

(*Continued from page* 1193)

per cent., use cantilever springs, and 45 per cent. of those using cantilevers drive through the spring. In plain figures, ten manufacturers out of 119 drive their cars through cantilever springs.

Analyzing first the method of taking the drive through the springs, there are two classes: those who employ the Hotchkiss drive, and those who do not. The Hotchkiss drive is that in which not only the forward propulsive thrusts are taken but in which the torque is also absorbed by the springs. Some of the cars which use the pure Hotchkiss drive are the Oakland, Imperial, Stearns, Apperson, Hudson, Haynes, Westcott, Empire, Cadillac and Mitchell. Those who use it favor it for its flexibility, primarily, and second for the saving in weight. This drive is not altogether new. Apperson had a car in the Savannah race of 1908 with this type of drive in connection with semi-elliptic springs. The way the springs are generally mounted on the Hotchkiss drive is to rigidly attach them to the rear axle with the front end secured by an unusually large bolt, through which the drive is transmitted. This bolt is of course securely anchored in a bracket, which is in turn riveted to the frame.

Spring Drive Flexible

There are advantages gained by the absence of several joints and shackles which are necessary with other types of drives. It is stated that it is bound to be quieter because it is more flexible and also that the car holds the road better with this drive. All companies using the drive advance practically the same reasons for its use, especially emphasizing the fact that the road shocks which would sometimes be communicated from the axle to the frame through stiff torque members are eliminated.

The amount of weight saved by using the Hotchkiss drive is estimated variously by different concerns. Oakland says 20 pounds, Imperial, on the other extreme, says 200 pounds. Between these figures there are Hudson, 50 pounds, and Haynes, from 25 to 50 pounds. Cadillac believes that the weight saved is the lower limit of 20 pounds. As regards the efficiency of the drive concerning slippage of the wheels, the general opinion is that there is no difference, although others believe differently, advancing as a reason that the taking up of the flexure in the springs eliminates slippage in starting and braking.

Cars which take the drive through the springs but the torque through other members state that they gain the advantage for flexibility in drive with the elimination of side sway and other strains. The big objection that those using the drive through the springs advance against the radius rods is the argument that these are apt to rattle. The fact that radius rods are used on 20 per cent. of the makes, however, would indicate that there are two well developed sides to this question which is still in the argumentive stage.

Many Using Cantilevers

The concerns which have adopted cantilever springs are Grant, Jeffery, King, Lexington, McIntyre, National, Paige, Pathfinder, Pilot, Pullman, Scripps-Booth, Singer, Sphinx, Stearns, Trumbull, Twombly, Westcott and Willys-Knight. Its chief advantage as a means of suspension is the lack of sharp rebounds. Beyond this, the other advantages are reduction of unsprung weight, a greater deflection for pound load, greater flexibility and the elimination of the cut in the body necessary with the three-quarter elliptic.

Whether the cantilever spring is used in connection with some sort of driving or radius rods to take the thrust of propulsion from the rear axle to the frame, or whether the cantilever is used as a drive member has much to do with its construction. When used for the drive, as for suspension, it is customary to stiffen the main leaf of the spring. When a torque tube or torque rods are used to take the starting and braking torque the main leaf is lighter.

The reasons for using the cantilever form of support are various. The cantilever springs allow a great range of action for a given length of spring, are more resilient, have more internal friction and hence show less need for shock absorbers. They are especially adapted for taking thrusts but not torque. The reason is that in comparison with other springs there is more metal in the line of thrust than in any other type. This allows for greater beam strength and a greater possibility of eliminating side sway. It is of course recognized that the amount of strength of the units taking the drive varies directly with the modulus of the section of the material in the line of drive.

As compared with the semi-elliptic the comparison is made that almost the entire spring weight of the semi-elliptic is unsprung, whereas in the cantilever it is practically all sprung weight, tending to make riding easier.

Wire Wheels Gain Slowly

While there is a slow increase in wire wheels, there is nothing like the deluge that was predicted a year ago. Only 7 per cent. are equipped with them regularly and 4.5 per cent. may offer them as an option. Some of those who fit them regularly are: F. R. P., Grant, Pullman, Scripps-Booth, Saxon, Twombly and Willys-Knight. Some who give them as an option are: Briscoe, Fiat, Lenox, Locomobile, Moline, Owen and Singer. This gives 11.5 per cent. as the maximum percentage of cars on which wire wheels can be secured at the regular purchase price. The wire wheels used are of the demountable and detachable types, and are distinguished by the fact that they are of lighter weight than the earlier wire wheels. The weight per wheel of a demountable 34 by 4 is 29.75 pounds for the light type and 31.25 pounds for the medium weights. For the heavy-weight rims, which are not as often used, the weight of the demountable wheel complete is given as 43.75 pounds. This is 203 pounds per set. These weights are for the number 3, 30 and 40 demountables manufactured by the Standard Welding Co. They may be taken for a fair sample of demountable wire wheel practice as it is at the present time.

More than half the chassis now have the gasoline tank at the rear. This is accounted for by the sudden growth of the vacuum feed system. In 1914 vacuum feed for gasoline was quite obscure, but this season more than 20 per cent. use it. The result in tank location has been the increase of rear tanks from 41 per cent. for 1914 to 51.1 per cent. for 1915. Cowl tanks have also increased from 13 per cent. for 1914 to 27.2 per cent. for 1915. Tanks under the seat are the losers. In 1914 46 per cent. had them in this location; in 1915 there are but 21.2 per cent. of underseat tanks. The vacuum feed means in reality a gravity feed to the carbureter, as the vacuum part of the system sucks the gasoline from the rear tank to a small tank on the dash or under the hood.

Pressure Feed Used Less

As would naturally be expected, from the shifting of tanks pressure feed has dropped, but reached its zenith in 1914, when 41 per cent. fed by pressure. In 1910 18 per cent. used the pressure feed system, and this grew to 19 in 1911, 25 in 1912, 35 in 1913 and 41 in 1914. In 1915 only 22 per cent. use the pressure feed. The Stewart-Warner vacuum feed is employed on 20.5 per cent., a position which it has gained within a year because in 1913 no cars were fed in this manner. The pressure-gravity fuel system, in which the fuel is fed by pressure to a gravity dash tank, has not taken a very strong root. Chalmers has it on one model, and this is about the extent of its use. The vacuum feed is used on all classes of cars, not merely on low-priced, high-priced or intermediate. It is used on all sizes of cars, and the number of manufacturers who have adopted it number more than 30, practically a quarter of the industry.

This method of feeding the carbureter has been adopted after experimenting to ascertain that the probability of mechanical troubles with the tank was very small. Its adoption generally eliminated a hand pump, a motor-driven air pump, two check valves and one line from the motor to the gasoline tanks. These parts, having to handle air at low pressures, are rather troublesome to keep tight and in good working order. The motor-driven air pump necessarily feeds a small quantity of engine oil through the pressure line to the tank, which makes trouble in cold weather by congealing. The vacuum feed furnished gasoline to the carbureter under a somewhat more uniform pressure than do the pressure feed systems.

Another advantage of the vacuum feed over the gravity with the tank in the cowl is due to the fact that the cowl tank must be soldered on account of its odd shape, with consequent danger of leak. It reduces the capacity of the gasoline supply, is noisy due to the splashing, is odorous, and it is inconvenient to fill. The vacuum feed retains the advantage of the gravity without these disadvantages.

Other reasons are on account of the low body lines necessary for an up-to-date car, and this necessarily cuts down the available space beneath the front seat. It has been mentioned in the motor review that one of the great advantages of the vacuum feed system is in the raising of the carbureter permitting greater accessibility.

Left Drive and Center Control

The movement towards left drive and center control which started in 1910 has continued without cessation. In 1910 but 2 per cent. used this combination; in 1915 79.5 per cent. are so driven and controlled. Right drive and right control have been traveling down the scale in about the same ratio as left drive and left control have been ascending. In 1910 93 per cent. had right drive and right control; in 1915 9.5 per cent. have remained faithful to their convictions in this respect. Right drive with central control went up the scale from 1910 to 1912 from 4 to 15 per cent. Since then it has fallen away until now but 3 per cent. use it. Makers who still maintain left control are 3.5 per cent. This has been almost constant since 1910. At that time it was 1 per cent., in 1911, and 1912 it was 2 per cent., in 1913 4 per cent. and 1914 2 per cent.

The high spots in starting and lighting systems, which will be fully treated later, are lighter weight, better electrical characteristics, better insulation, simpler meshing of starting motor to flywheel and quieter drive. Trends of design center around the simplifying of the electrical installation. An example of this is in the use of the single-wire system which is now on more than 70 per cent. of chassis using electric starting. The almost universal adoption of flywheel connection for the starter is another feature. In 1914 62 per cent. connected the starter to the flywheel. The percentage is now in excess of 85. The Bendix gear connection for the starting motor to the flywheel is another feature which is on the increase. Six-volt systems retain their supremacy. Those who are using the combined lighting, starting and ignition system are on the increase, and Delco has to its credit this season over twenty-five installations on different chassis. Over 110 chassis, however, still continue to use the magneto.

In body work the movement towards the moulded design has been practically universal. The sloping hood and flush-sided body, with its low lines, has won popular approval for the sake of appearance.

Bodies are larger for two reasons: the engine bonnets are shorter. The result has been that more space can be devoted to seating capacity. The car for 1915 has more leg room in the forward compartment than its immediate predecessor. The width of tonneau seats has been increased and the 48-inch seat is common even on cars of low and medium price.

The touring car, as usual, holds its own. Under $1,250 there are seven makers who specialize only on touring cars. These are Alger, Detroiter, Dodge, Interstate, R. C. H., Sphinx and Vixen. Among the $1,500 makes there is only one, Monarch. In the $2,500 class only three makers specialize on the touring car alone. These are Luverne, Lyons-Knight and Speedwell.

As would naturally be expected, a concern would specialize on a runabout only among the cheaper cars. These are Argo, Dile, Herreshoff and Rayfield. Metz was one of these until the middle of December, when they announced a touring car, which was the first they had ever built.

Four-passenger bodies are manufactured by a number of concerns, but in the low-priced class. In the $1,500 class, Cole, Corbitt, Crow, Great Western, Kline, Norwalk, Pratt and Velie make them. In the $2,500 class, Crow, Great Western, Haynes, McFarland and Pratt sell four-passenger cars. Above $3,000 there are Locomobile, Marmon, Pierce, Republic and Stearns. In the closed bodies Ford stands alone among those listing Sedans below $1,250. Kissel is the only name found among those listing Sedans between $1,250 and $1,999. The cheapest limousines are in the $2,500 class, which is represented in this respect by Hudson, Jeffery, Kline and Stearns.

Only two list landaulets below $3,000. These are Cadillac and Hudson. There are six concerns listing Berlins, namely: Cadillac, Fiat, Franklin, Locomobile, Peerless and Stevens.

Equipment is better and lighter than ever. The one-person top is the feature this year, neglecting starting and lighting for the moment, on the low-priced cars. Practically every car is sold fully equipped at the purchase price. More cars have speedometers and clocks than ever before. One of the big points in equipment on the higher-priced cars for this year is the cord tire. Among the concerns who are furnishing them are White, Franklin, Pierce, Marmon and Owen. The gain in efficiency has been variously estimated. Franklin puts it at 18 or 19 per cent. in hill-climbing ability and states that tire mileages are much higher. Goodrich tests on the Silvertown cord show a 23.6 per cent. gain in coasting efficiency. Lower air pressures and less heating are also advantages.

Control Features Improved

The mounting of control features has been improved. Adjustable pedals are used almost universally. The dash instruments are better placed. Overland, during the year has gone over to the method of mounting the lighting, starting and ignition switches on the steering column.

With all this increase in comfort, economy, appearance and durability, the price of the car has gone down. Last year an upward trend was noticeable in the selling price of cars, but a study of the price chart shows that that price went up from $2,214 for the average car in 1910 to $2,560 in 1911. In 1912 it went down to $2,508. In 1913 makers started to put on electric cranking and more equipment, so prices took a jump to $2,585 that year. This tendency was continued for 1914, when the price reached the high-water mark of $2,685. For 1915 it is about where it would have been if the downward trend of 1911 and 1912 had continued—$2,005.

Vulcan Gearshift Stronger and Lighter

Magnetic Pull for Gearshifting Increased—Current Consumption Reduced — Endurance Test Demonstrates Stability

THE Vulcan electric gearshifter introduced last year, and which has been taken over by the Cutler-Hammer Mfg. Co., Milwaukee, Wis., is now being manufactured in an entirely changed form, incorporating, however, the original principle of the Vulcan, namely, that of sliding the gears on the shafts of the gearset by electro-magnetic force, and also having the entire control of gearshifting centralized in the center of the steering wheel. The design has been changed, including the solenoids, the size of the coils and the plungers. Added to this, the neutralizing device is different as is the selector switch and the master switch mechanism, in fact, little of the old Vulcan remaining except the name, and the employment of the basic principles.

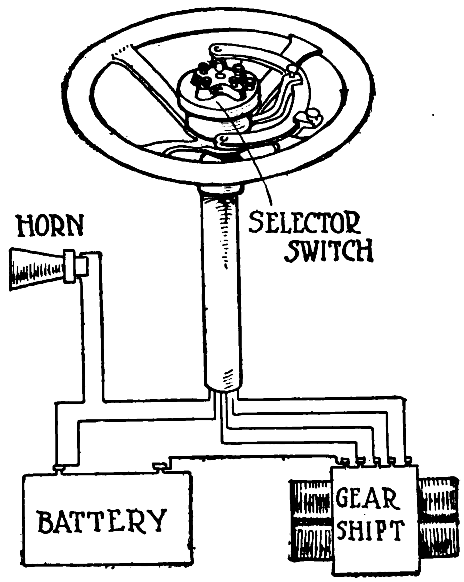

Fig. 1—Diagrammatic illustration of improved Vulcan electric gearshift, showing simplicity of wiring system

20 Pounds Added to Car

In its improved form, the Vulcan shifter adds a total of 36 pounds to the gearset, but when the weight of the control lever and its protection are taken into consideration, the added net weight is little over 20 pounds. In its new form it is a lighter and more compact mechanism than formerly. It is also much stronger, in fact, so great is the increase in the electro-magnetic pull that the inspection of the coils of the electro-magnet includes the lifting of a 90-pound weight vertically with a 7-8-inch airgap. Any coil cannot lift this weight is rejected.

Little Current Required

The question of the amount of electric current needed in this gearshift work is frequently raised, but it can be considered a negligible quantity. So slight is the current needed that no appreciable drain on the starting or lighting battery is noticed, in fact it is stated that the total current consumed in shifting gears does not exceed .005 ampere-hour per shift or sufficient to supply a set of lamps 4.5 seconds.

Tested for Endurance

The Cutler-Hammer Co. has tested their present design out to the fullest, by attaching to a gearset driven by an electric motor. The gearshift was operated 60 times per minute, the tester pressing the buttons on the selector switch alternately. The device was operated in this way 294,491 times after which it was examined for indications of mechanical or electrical defects, and the closest inspection failed to show any indications of weakness or deterioration.

To secure some definite conception of the current consumption and to determine the number of shifts that could be made using a 12-volt, 80-ampere-hour battery without recharging, the same method of test was followed and 134,490 gearshifts made. Calculating on a basis of 100 shifts per day, 365 days per year, and considering the total number of operations, this test equals 4 years of constant car service.

In describing the Vulcan gearshift it should be remembered that in making any gearshift by the conventional hand method the lever is used to slide a gear on one shaft into or out of mesh with a corresponding gear on a parallel shaft constituting a part of the gearset. With the Vulcan gearshifter these movements are accomplished by electro-magnetic force, there being a separate solenoid for each speed change. On the steering wheel is a series of buttons for selecting the gear desired.

Current is sent to the proper solenoid by a series of buttons in the center of the steering wheel, these buttons replacing the gearshift lever as the operating means. A master switch is interconnected with the clutch pedal in such a way that the solenoid is not energized until the clutch pedal is pressed clear out, a sufficient throw being allowed between the complete de-clutch position and the operation of the master switch, to permit throwing out the clutch without shifting gears. In this way a speed combination may be predetermined by setting a button on the steering wheel, but the actual shifting of the gears does not occur until the clutch is thrown off at some later time.

The gearshift consists of two units: the shifting assembly or group of magnets attached to the gearset case and the selector switch, or push button group, located on top of the steering column in the center of the steering wheel.

The selector switch, which is carried on the wheel, is made up of a number of buttons, one for each speed and one for neutral which has no electrical connection. There also is a button in the center for operating the horn. The top of the switch carries a locking plate for locking any button which may be depressed and also carries an interlock which makes it impossible to press down more than one button at a time.

Wiring System

The wiring is simple. There is one lead passing from each coil through a terminal block to its particular speed button on the selector switch, and the other lead from the coil is joined to a neutral wire directly through the terminal block to the battery, with the master switch intervening. Another wire from the battery passes through the terminal block to the contact of the selector switch which is common to all speeds. The current travels from one terminal of the battery, through the depressed push button, around the coil selected and back to the other terminal of the battery.

The terminal block mounted on the shifted case is introduced in order to make it easy to remove the gearset without disturbing the wires. It is made up of the required number of male and female terminals for each speed. These are insulated from each other by fiber blocks, but are securely fastened together so as to be a unit. These terminals are each of a different size so that should it be desired to pull out

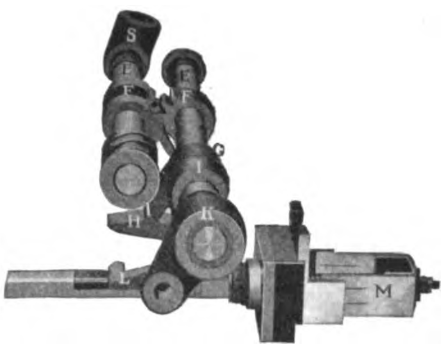

Fig. 2—End view of the shifting mechanism, including the neutralizing mechanism and the master switch

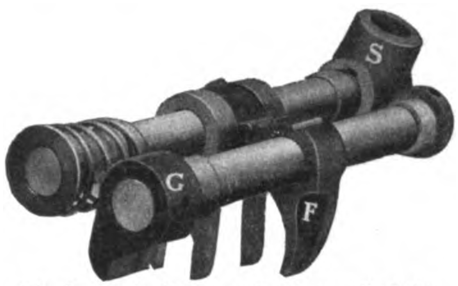

Fig. 3—Neutralizing mechanism unit of the Vulcan electric gearshift

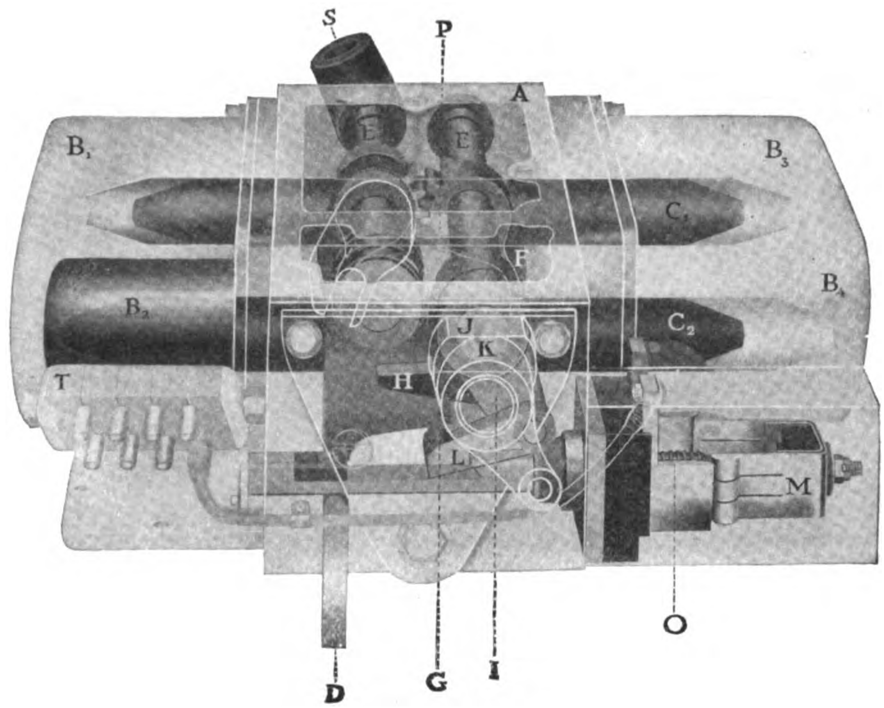

Fig. 4—Phantom view of the entire shifting mechanism used in the Vulcan electric system as it looks applied to a gearset

the wires there is no danger of getting them mixed up because no wire will go on any terminal except the right one.

Magnetic Pull Increased

It is pertinent here to point out some of the features wherein the Vulcan electric gearshift has been improved since its redesign by the Cutler-Hammer engineers. In the first place, the pull of the electric magnets has been greatly increased without increase of weight or size by a redesign of the housing of these magnets. Instead of having a separate case for each magnet, all the magnets on one side, two in the case of a three-speed gearset and three in the case of a four-speed gearset, have been covered by a common housing of cast iron which in addition to its protective function, forms a part of the magnetic field and thus increases the intensity of the magnetism and so increases the pull on the armatures. There are only two armatures or shifter rods for a three-speed gearset and each end is inclosed in a separate magnet winding. The pull has been further increased by a change in the shape of the ends of the pull rods or armatures. Formerly the ends of these armatures were flat, but they have been tapered off to a conical shape, so that the magnetic field becomes more intense as the armature nears the inner end of the coil or the end of its throw, this giving not only a stronger pull but a snappier one, the speed increasing as the motion proceeds.

Conserving the Current

Another improvement is in the interconnection of the master switch and the clutch pedal. In the early type the full battery current was flowing through the coils as long as the clutch pedal was completely depressed. This meant that sometimes the current was permitted to flow through the system after the gears had been shifted and the current thus wasted. In the new design the master switch is thrown out automatically when the action is completed, regardless of how long the clutch pedal might be depressed. This provides an additional saving of current. The whole equipment appears considerably more rugged and substantial than did the earlier type and probably offers less chance of disarrangement in service.

To take up the design and operation of the gearshift in detail reference is made to Figs. 2, 3 and 4, Fig. 2 being an end view of the shifting mechanism including the neutralizing mechanism and master switch. Fig. 3 is a view of the neutralizing mechanism alone and Fig. 4 is a phantom view of the entire shifting mechanism as applied to a gearset, the arrangement shown here being that for the gears in third speed, that is, direct drive. In all three figures the letters refer to identical parts.

The electric gearshift mechanism consists of a case *A* attached to the gearset housing. This case carries the magnets or solenoids *B*, these in turn surround the armatures *C* on which are mounted the shifting forks *D*, which move the sliding gears. In this case, also, is carried the operative mechanism by means of which the gears are mechanically drawn to their neutral positions through a connection with the clutch pedal. The case *A* is divided into two compartments, the smaller of which is a pocket in which the mechanism for neutralizing the gears and operating the master switch are carried.

The neutralizing mechanism consists of two operating shafts *E* on which the neutralizing cams *F* are mounted. One of these shafts carried the pawl *G* which in turn engages with a latch *H*. This latch is carried on the rocker arm *I* which is mounted on the shaft *J*. Upon the opposite end of this shaft is mounted the operating lever *K* through which the connection with the clutch pedal is made. The rocker arm *I* also carries the switch operating pawl *L* which engages with the stem of the master switch *M*.

How the Mechanism Works

Assuming that all gears are in a neutral position and it is desired to start, the first speed button on the selector switch in the center of the steering wheel is depressed, closing one break in the electric circuit. The operating lever *K* and the shaft on which it is mounted are rotated and the master switch *M* is pulled into engagement through its connection with the operating mechanism *L* which engages the switch stem. As the gear moves into mesh, and is within 1-8 inch from being home, the pawl *G* falls back, due to the pull of the magnets against the neutralizing cams *F*, causing it to strike against the trigger *N* which is attached to the switch operating pawl *L*. This action causes the pawl *L* to be raised out of engagement with the stem of the master switch and

The Improvement of Spring Suspension-III

By M. C. K.

(Continued from issue of December 10)

As has been seen, the movements of a vehicle without springs or springy construction elements follow closely the inequalities of the road, and the objections to springless construction, which for thousands of years were obviated mainly by means of soft cushions and leather straps, lie in the severity of the shocks received and in the fact that the movements of the vehicle body and load are as large and as sudden as those of the running gear. The waste of driving power scarcely came under consideration till motor vehicles made their appearance. It is perhaps useful to notice that springs have not yet conquered universally in practice. They were not considered indispensable or even desirable for very smooth roads, such as railroads, until speeds became high and the wear and tear of rolling stock were systematically looked into, and for railroad practice their stroke is still sharply restricted, while devices for varying their flexibility according to the load are much more widely employed than is the case in other applications. On the other hand, practice has never fully ratified their use for speedy work on very rough roads, such as may be demanded of artillery. And they are considered superfluous if not harmful for very slow and heavy work on any kind of road. Their usefulness is in fact recognized mainly for medium speeds on roads of medium roughness, and the development now taking place is aimed at the expanding of their range of utility by changes in their construction.

Averages and Safety

These things are so perfectly well understood in a general way that they are seldom mentioned in detail, and their bearing upon the subject of improvement easily escapes attention. Especially, it seems to be overlooked sometimes that the springs, though intended to keep the load-level constant and to render all movements less abrupt, often cause the movements of the load to be, for a brief period, not only more numerous but also larger than they would be without the use of springs and, under certain less frequent combinations of road conditions and vehicle speed, even cause shocks more destructive and uncomfortable than those which would be received in a springless vehicle under the same road and speed conditions. While the beneficial average effects of springs make them indispensable, counting decisively when only comfort is considered, the exceptional effects can of course not be ignored when safety for structure, load and occupants is involved, as safety does not depend upon average effects but upon the extremes; not primarily upon wear or fatigue of metal, or other accumulative factors in deterioration, but upon accidental fractures.

Importance of Exceptions

As the advantages to be obtained by using springs are also invariably discounted in advance by building vehicles less robust than anybody would think of building them without springs, the extraordinary stresses which are produced exceptionally are eventually found to form a most important division of the subject, especially where utility vehicles are concerned, since in these the safety against fractures—of both vehicle and load—is the main object of spring suspension.

These rather obvious reflections drawn from well-known practice to assist in justifying a theoretical comparison of the things that take place under different conditions of vehicle construction, are suggested by the need of determining the shocks and retardations occurring in the case of a springless vehicle, when, under the influence of a road obstacle, it describes the movement illustrated in Fig. 5.

Fig. 6 shows this movement again, with additional indications of the factors in shock and retardation.

The simplest manner of figuring is based on considering the kinetic energy which is abstracted from the moving vehicle and the speed which can be produced with what is left.

Exactness Illusory

Two methods have been proposed for estimating this retardation, any exact calculation being complicated by the wheel action and the irregular shape of a four-wheeled vehicle. Both methods are presented, the first one in small type.

It was seen that the front portion of the vehicle would make a leap 3.18 feet high to clear the 3-inch high obstacle, if only the velocities were decisive and no energy lost in shock. The energy required for such a leap, though it remains imaginary for a springless vehicle acting against a ridge of the shape under consideration, is therefore approximately equivalent to the energy abstracted for the vertical component of the shock at the front axle, although this energy in the absence of all elasticity is spent mostly in shock and only to a small degree in load lift. This is clear, as the force of the blow against the ridge does not depend upon what happens afterwards but only upon the vehicle and the road condition.

In accepting this method of figuring it is necessary to consider that the nature of a wheel permits the vehicle to clear the obstacle by following the lines of smallest resistance. But in assuming that axle B moves in a straight line to C instead of being compelled by friction at A to follow curve BC, and figuring the height of the leap as it would be if the straight line were followed, the horizontal element in AB is not considered, and it must therefore be figured separately, and the retardation involved in it must be added to that caused by the leap.

A leap which is arrested by gravitation at a height of 3.18 feet and involves a weight of 1,000 pounds represents the work of 3,180 footpounds and is numerically identical with the force required for imparting to 1,000 pounds an initial velocity of 14.25 feet per second. (This force is conceived as developed in 0.01755 second, during the contact of the wheel with the ridge, as referred to before, and this time element, indicating the greater or lesser violence expressed in speed, may not have an influence on the retardation, but in practice it means everything, almost, with regard to destructiveness).

The total energy of the vehicle being $\frac{1}{2}\, mv^2 = (3{,}000 : 64) \times 50^2 = 117{,}187$ footpounds, from which there is to be deducted 3,180 of the same units, the remaining speed v_1 of the vehicle is determined by the equation:

$117{,}187 - 3{,}180 = 114{,}007 = \frac{1}{2}\, mv_1^2 = (3{,}000 : 64) \times v_1^2$,
so that $v_1^2 = 64 \times 114{,}007 : 3{,}000$ and $v_1 = 8 \times \sqrt{38{,}002} = 8 \times 6.16 = 49.28$ feet per second.

The speed reduction due to the vertical component of the blow is thus 0.72 feet per second, but the horizontal component must also be figured.

It is seen directly from the diagram that the two components are in the proportion of 17 inches for the vertical one to 10.53 inches for the horizontal one, and, the vertical one being equal to 3,180 footpounds, the horizontal one would at first glance seem to equal 1,969.73 footpounds. But the value of the vertical component is obtained by figuring from the movement imparted to a weight of 1,000 pounds, while the horizontal thrust is determined by a body weighing 3 times as much. As a corrective to the graphic proportions, 3,180 footpounds may therefore be multiplied by 3, making 9.540 footpounds, and from this value the proportion of the horizontal component may be taken, making the latter $9{,}540 \times 10.53 : 27.53 = 3{,}643$ footpounds.

In the previous equation it was therefore $3{,}180 + 3{,}643 = 7{,}823$ which should have been deducted from 117,187, making $v_1^2 = 64 \times 109{,}364 : 3{,}000$ and $v_1 = 8 \times \sqrt{36{,}451} = 8 \times 6.04 = 48.32$ feet per second, instead of 49.28, and the total speed reduction of the vehicle due to the passing of the front wheels over the obstacle 1.68 foot per second.

Out of the 7,823 footpounds of energy lost only 3" × 1,000 pounds = 1/4 × 1,000 pounds = 250 footpounds represent lift, while the rest, or 7,573 footpounds, represent shock, but no division in vertical and horizontal shocks can be figured from the data used.

The More Direct Way

The other and perhaps safer way of estimating the loss of kinetic energy, while also getting values for some other factors, is as follows:

If B were the center of gravity of the vehicle, the kinetic energy, 117,187 footpounds, would at the impact with A be resolved into two components, BA in the direction of resistance and another, BL, in the direction of possible movement. As the possible movement is an arc, BC, described with a 20 inch radius around A as the center, BL must be tangential to this arc and at a right angle with BA. As elasticity is supposed to be lacking, and no rebound therefore can take place from A, no other direction than BL is possible, and BL therefore would represent the energy remaining after the shock, turning with the wheel during the progress of the shock; and BA would represent the lost energy spent in shaking the earth and stressing the wheel and the rest of the vehicle. BA would have the value of $\frac{1}{2}mv^2 \times \cos \alpha$ and BL that of $\frac{1}{2}mv^2 \times \sin \alpha$, if the object were to determine forces equivalent to the original energy for driving the vehicle in the direction NB, but for the present purpose these values indicate only the proportions in which the total energy is divided.

It is also noticed that BL goes on increasing in value in the measure as the axle describes the arc BC, finally reaching the value of 117,187 minus x (x being the energy lost), and that BA goes on decreasing in value toward zero. It is therefore the mean values which must be used for an estimate.

A Student's Question

(And, seeing that the retardation must be strongest at the beginning of this movement, a question is suggested as to whether the speed of the vehicle can really be reduced most in the beginning of the shock and afterwards can pick up. The answer must be that the horizontal speed of B is reduced most in the beginning by reason of the arc-movement, the tangent BL giving the direction, which veers from BL to CM, but that the vehicle as a whole cannot be retarded one moment and pick up the next, except under the influence of its motive power or possibly by means of energy stored momentarily in springs or tires. The opposite view would mean the creation of energy from nothing, since $\frac{1}{2}mv^2$ at any moment measures this energy. A possible function of springs and tires is here at the same time brought into view).

It is not necessary to find α in degrees, as it is known that 20" $\sin \alpha$ = 17" and 20" . $\cos \alpha$ = 10.53", and the same proportion holds good for any other radius than 20 inches. Dividing in this proportion, one has BA = 117,187 × 10.53 : 27.53 = ∼ 44,750 footpounds, and the mean between this and zero is 22,325 footpounds.

This figure for the lost momentum is however not in accordance with the data, as B is not the center of gravity of the vehicle but only the point at which the weight of 1,000 pounds is supported. To simplify the estimates, the center of gravity is supposed to lie in the line NB, and while horizontal shocks can be resisted at B by the energy of the whole vehicle and a mass determined by 3,000 pounds of material, the vertical shocks can be delivered only against 1,000 pounds. As action and reaction must be equal, the value for BA = 22,325 footpounds may therefore be modified by resolving BA into its horizontal and vertical components and dividing the latter by 3,000: 1,000 = 3. (It would be more correct to figure with the velocity imparted to 1,000 pounds at rest, but this is handier and perhaps near enough.)

The Wheel Action

Moreover, the horizontal component is affected by the rotation, or capacity for rotation, of the wheel; the situation is not the same as if a wheel fixed upon its axle were shoved over the ground. (This element enters, for rear wheels, if the obstacle is met a moment after the wheel has been locked by the brake—a frequent occurrence, perhaps accountable for accidents to springs and spring shackles). For normal driving, the horizontal component AH can be again resolved into AJ, representing 17: 27.53 of its value, which is spent in overcoming friction at A, and another component running back in the direction of the wheelhub and equal to 10.53: 27.53 of the value of AH.

The modified value of BA is now obtained: The vertical component of BA is 22,325 × 17: 27.53 = ∼ 759,050: 55 = 13,801 footpounds, and this divided by 3 makes 4,450 footpounds of vertical shock.

The horizontal component of BA is similarly found to be 8,524 footpounds, making the total of abstracted energy 4,450 + 8,524 = 12,974 footpounds, and, on the same principle that was applied before, this gives the retardation from $v_1^2 = \frac{117,187-12,974}{3,000} \times 64$ and $v_1 = 8\sqrt{34,737} = 8 \times 5.89 = 47.20$ feet per second.

Chance for Critics

There is seen to be a considerable divergence in the results of the two estimates, and this illustrates the tricky lapses for

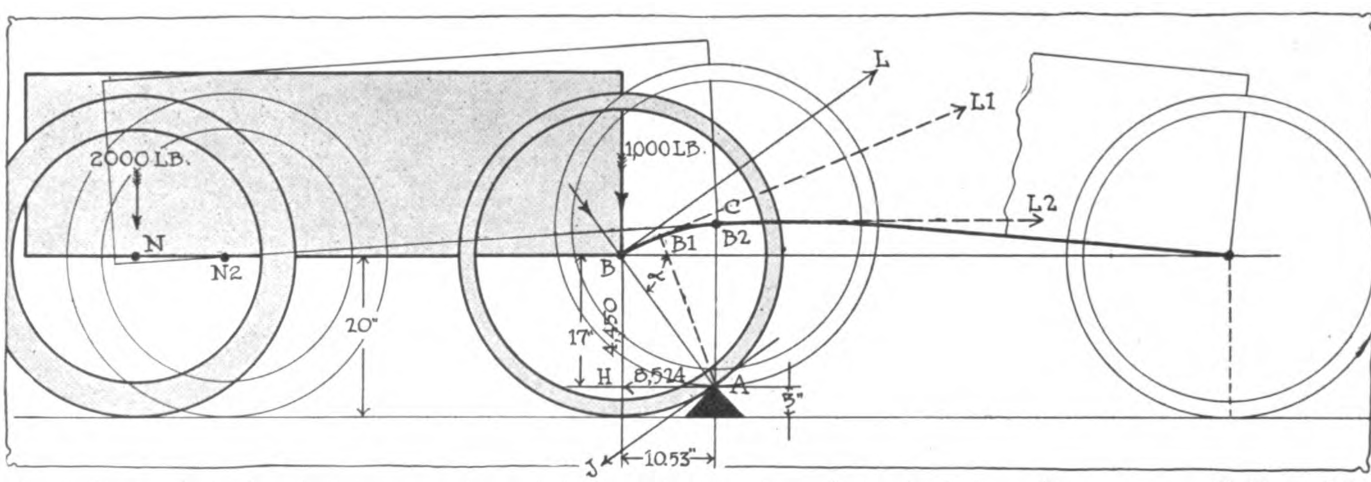

Fig. 6—Diagram indicating shock stresses and retardation occurring when front wheels of springless vehicle pass over a 3" ridge at 50 feet per second. Heavy curve shows course of axle before and after surmounting obstacle. Rear wheel curve similar but shorter

which stress sheets in automobile construction have become notorious, usually rendering several trials by different persons necessary before errors in the estimated or omitted factors are brought to a working basis. For present purposes the figures of the second estimate may perhaps be used, however, as its errors will probably appear in the same proportions whether it is applied to a springless or a spring-suspended vehicle. Still there is evidently room for corrective ideas to develop the handiest and best method; so much more useful as the estimation of stresses, wherever exact calculation is impracticable, enlists new thought for the neglected fundamentals of spring action and has a tendency to clear up details not otherwise thought of. Under all circumstances no better figures can probably be devised for measuring the action of springs and tires, their advantages and their shortcomings, than those pertaining to the action of springless vehicles.

The Destructiveness

According to the figures of the second estimate, the retardation becomes 2.80 feet per second as soon as B has reached to the position of B_2, which is the same as C, and BL has been turned to the position of BL_2. It now becomes possible to figure somewhat on the destructiveness of the blow. The entire force of it (= 12,974 footpounds) minus 17 : 27.53 of 8,524 (being the tangential portion of the horizontal component—that which tears pieces out of solid-rubber tires when a sharp rocky edge is struck, springs being rather ineffectively arranged to reduce it), in all 12,974 — 5,269 = 7,705, is delivered against axle B during the time when the vehicle presses against the ridge and turns the wheel around A. The horizontal average speed here ranges from 50 to 47.20 feet per second, a mean of 48.60. From this, the time occupied in passing from B to C, a horizontal distance of 10.53 inches, is figured to be 0.01805 second, and, if a blow sustained in this brief period works in practice as if it were instantaneous, the materials should be able to resist the whole force of it, the 7,705 footpounds. The blow may be examined with regard to the pressure on the axle and bearings by applying the formula

$$ks = \tfrac{1}{2}\,mv^2 \text{ or } k = \frac{m}{2s}\,v^2 \text{ or } s = \frac{m}{2k}\,v^2$$

in which k is pressure in pounds and s the space through which it is applied, this space being in the present instance the length of the arc BC, easily determined.

Considering the blow instantaneous and $s = 1$ foot, one has $k = 7{,}705$ pounds of pressure, directly on the bearings.

Slow Stress Transmission

But if the blow cannot be considered instantaneous, with reference to the nature of the material, especially the velocity in the molecular transmission of stresses, the pressure of 7,705 pounds must be considered as distributed decreasingly. If 4 periods make the action for each period equal to that of an instantaneous shock, in effect on the materials, the distribution would be somewhat like 5,000 pounds for the first fourth of curve BC, 2,000 for the second fourth, 600 for the third and 105 for the fourth. This means reducing maximum pressure on bearings nearly 50 per cent.

In the supposed case of an entirely unelastic vehicle, the question of the rapidity in transmission of stresses does of course not arise, but if wood is compared with steel as a wheel material—for heavy trucks, for example—and it is assumed that wood is the slower transmitter of stresses, it is evident that the subdivision of a shock stress extending over only such a short period as 0.01805 of a second may become of interest and may influence construction—as evidenced at present by the practically compulsory use of solid rubber tires with cast steel wheels.

(To be continued)

Vulcan Gearshift Stronger and Lighter

(Continued from page 1273)

the master switch snaps out instantly due to the action of the master switch spring *O*, thus breaking the electric circuit. The actual time of the engagement during which current is being drawn from the battery is less than 1-3 second.

Being in first speed, and desiring to proceed to another, another speed button upon the selector switch may be depressed at the convenience of the driver. Then, when it is desired to shift, the clutch is fully depressed as before, this action rotating the operating lever *K* and its shaft which carries the rocker arm *I* and its attached mechanism. As the first gear or whichever gear has been previously selected is in mesh the latch *H* is in engagement with the pawl *G* of the neutralizing mechanism, and as the operating lever and rocker arm *I* are rotated the latch *H* presses against the pawl *G*, causing both the neutralizing cams *F* to rotate toward the center, due to the fact that they are enmeshed through the teeth *P*.

On the central side of the shifter forks *D*, we have a boss and as the neutralizing cams *F* rotate toward the center, they press against the boss or whichever side the gear is in engagement. This mechanically pulls the shifter fork and the gear with which it is engaged back to neutral position—before the next shift can be made. As the gear reaches neutral position the end of the latch *H* strikes the knockout pin. This action releases the latch from engagement with the pawl *G* and as the operating lever *K* is moved ahead by the foot of the driver on the clutch pedal, the switch operating pawl *L* pulls against the switch stem, closing the circuit at the master switch, as before explained. The electric circuit is complete, the current flows from the battery through the solenoid selected and the proper gear immediately jumps into engagement. This action is the same for all speeds.

Should it be desired to stop, the neutral button in the selector switch is pressed. This action throws any other button which may have been depressed out of contact, that is, it automatically raises any other button which may have been depressed previously.

When it is desired to stop, the clutch pedal is fully depressed, as before explained, and the operating lever *K* moves ahead. The neutralizing cams *F* pull on the boss on the shifter forks, the same as if a shift were to be made. The master switch *M* also will come into engagement as before. However, as the pressing of the neutral button has broken all contacts in the selector switch, a circuit is not made and the electric current does not flow. Therefore, as none of the magnet coils are energized, the gears remain in a neutral position.

Made in U. S. A. Exhibition March 6-13

NEW YORK CITY, Dec. 29—A "Made In The U. S. A. Industrial Exposition" will be held at the Grand Central Palace, this city, March 6 to 13. This exposition is designed to show American made and grown products in practically all branches of business.

The exposition committee includes a number of prominent automobile men, including George Pope, president of the National Assn. of Manufacturers; C. B. Warren, president of the Board of Commerce, Detroit; Lee Anderson, president, "Made in the U. S. Committee," Board of Commerce, Detroit, and A. L. Riker, vice-president, the Locomobile Company of America, Bridgeport, Conn.

Glass Radiator Betrays Poor Circulation

Flow Often Up, Instead of Down, Is Brought Out at S. A. E. Discussion—Uneven Distribution of Air Through Radiator a Cause—Humidity Has Large Bearing on Cooling

NEW YORK CITY, Dec. 29—At the regular monthly meeting of the Metropolitan Section of the Society of Automobile Engineers held tonight, the paper presented was, Radiators and the Cooling of the Car, by Howard Greer, Jr., chief engineer, McCord Mfg. Co. This same paper was presented before the Indianapolis branch of the S. A. E. in November and was published in the December 10 issue of THE AUTOMOBILE.

There were many interesting points brought out by the discussion which followed the paper. Mr. Greer stated that an excellent scheme for determining the vagaries of water circulation in a radiator was to construct a radiator of glass and then place very fine boxwood sawdust in the cooling water, this particular sawdust being selected because its specific gravity is about that of water, and therefore it is held in suspension instead of floating as would most kinds of sawdust. It is found that in some tubes the circulation is up when it should be down and that all sorts of currents are set up which hinder the circulation. By properly distributing the flow of air through the radiator and at the same time using baffles to give an even flow of water through all parts these troubles can be avoided.

Not only does the water circulate through the radiator in unexpected ways but also the flow of air through different parts of the radiator is not uniform. In fact there are many examples where the movement of air at certain points in the radiator has been out towards the front of the car instead of in. The difficulty is to supply a fan which will suck just as much air at its center as it does at the blade tips, in other words, produce a uniform flow. Then there is also the disadvantage that the fan covers a circular area, and the radiator is generally rectangular in shape. Uniformity in flow can be produced, however, by the proper design of the fan and by shrouding it in a metal cover. In this way the corners of the radiator are subjected to almost the same suction as portions directly in front of the fan. An objection raised against the shrouding of the fan was that in case the fan belt broke and it was necessary to run without the fan, the cooling would not be as effective because the natural circulation due to the motion of the car would be hindered by the shroud.

Mr. Greer stated that in the average car when a speed of 25 miles per hour was reached, the flow of air due to the motion of the car was about equal to that caused by the fan and that above this speed the fan was a hindrance rather than a help. Ludlow Clayden, a British engineer, bore out this statement by saying that several owners of Daimler-Knight machines have found that more power could be obtained, except at low speeds, by disconnecting the fan, although the reason more power was obtained might have been due to the fact that the motors ordinarily ran too cool.

That it is folly to split hairs over the efficiency of a fan and then not apply it to the radiator so that full advantage of its efficiency can be taken was also shown. The fan should cover as large a part of the radiator as possible and if it does not there is no great advantage in high efficiency.

More uniform cooling is possible where the fan is placed several inches from the radiator but there is not room in the ordinary car for this to be done. Overheating troubles can be helped and sometimes overcome by fitting a shroud. In one case the transfer of B.t.u.s was raised from 700 to 1,100 by so doing.

Disposal of Air

Another important point related to fan efficiency is the disposal of the air after it passes through the fan. Many makers take careful steps to bring a large amount of air through the radiator and yet make no provision for its disposal. The flow of air is often hindered by starting and lighting units placed in close proximity, by horns and piping. The mud pan is a tight fit under the flywheel and the dash comes down close to the top of the flywheel so that it often happens that there is little room for the air to make its way out.

Slightly better efficiency in the hands of the average owner is obtained by the thermo-syphon system, due mainly to the avoidance of pump troubles. This system is heavier than the pump system and it is very necessary for uniform circulation that great care be taken in designing the water jackets, otherwise pockets will be formed in which water will stagnate until it becomes very hot or until a little steam is formed, when it will flow up to the radiator with a rush due to its much lower specific gravity.

Regarding the care of the radiator in Winter, it was stated that the best anti-freezing agents were denatured alcohol, glycerine or a mixture of the two; the plain alcohol is preferable. Acid-free glycerine is very expensive and hard to obtain.

Where too effective cooling for cold weather driving is obtained it is better to cover part of the radiator than remove the fan belt.

Humidity Important

An interesting fact was brought out regarding the overheating of some motor-driven sledges which were built for Antarctic exploration. It was found that they overheated badly when they were taken to their destination, although they ran cool during extensive tests in England. The explanation was that the Antarctic air lacked humidity, and that this factor must be taken into account in designing a cooling system. The addition of a small amount of moisture makes considerable difference in the specific heat of the atmosphere, and when this moisture is entirely absent, as it is near the Poles, the low temperature is not sufficient to offset the effect of the dry air. Similar experiences as to the effect of humidity have been found even in these latitudes.

The question of the practicability of a solderless radiator was brought up, the principle suggested being similar to that employed in steam boiler construction, but it was said that the objection was the cost—the public would not pay for such a radiator although successful experimental ones had been constructed both here and abroad.

In answer to the question as to the best way of mounting a radiator, Mr. Greer stated that the shell which houses the core should first be mounted in the chassis by the use of side brackets, trunnions or by bolting the bottom to a cross-member of the frame. Inside of this shell the core should be suspended by six or eight bolts held flexibly by spring washers.

Mr. Clayden brought up the question of mounting the radiator on the front of the crankcase and thus relieving it of the strains incident to chassis twisting and turning. Mr. Greer said that it is a question whether the motor vibrations, although smaller, were not worse than those due to the chassis, especially in view of the fact that the motor vibrations were regular. Unless the radiator is specially built to withstand these small strains it would soon be shaken to pieces. This method of suspension has found favor on two or three Italian cars.

In answer to the question as to the most desirable number of fan blades the speaker said that above 16 inches diameter six blades were as a rule best, but below this diameter four blades were preferable. However, one of the most efficient fans was a two-bladed French design.

NEW YORK CITY, Dec. 28—The Maxwell Motor Co., Detroit, Mich., recently issued a 416-page Master Price Book for the use of dealers and owners of all the old models. The book gives numbers, names and prices of parts, instructions on ordering, etc., for 164 different models. It is divided into sections, and each section covers all the models of one make of car. For example, the Stoddard-Dayton section is printed on yellow stock, the Brush models on pink paper and the Columbia section is made up of buff stock.

DETROIT, MICH., Dec. 28—Charles E. Van Horne has resigned his position of manager of the commercial car department with the Studebaker Corporation and has been succeeded by Henry Myers, manager of the Studebaker branch in Boston, Mass.; successor of Mr. Myers in Boston is George N. Jordan, traveling sales representative of the Studebaker Corporation in New England.

DETROIT, MICH., Dec. 29—Paul H. Bruske, who has been publicity manager of the Studebaker Corp., has resigned and will become manager of the racing team of the Maxwell Motor Co., beginning January 1.

DETROIT, MICH., Dec. 29—Claude A. George, for many years with the export department of the Willys-Overland Co., sailed last week for London as export sales manager of the Signal Motor Truck Co., and of the O. K. light delivery truck company.

Little Truck Show

IT is now 2 years since we have had the motor trucks with us at an annual show, but the arranging for a "commercial vehicle division" in the present show, where truck makers can establish temporary headquarters and meet dealers, suggests how many truck makers have missed the annual show, and how meeting with out-of-town dealers has been practically cut off. The truck industry today needs more dealers in many quarters; and with not a few dealers there has been growing the feeling that the truck business is harder than the passenger car field, requires more financing and is more susceptible to ups and downs in close coincidence with business conditions, a situation which has never been so pronounced in the passenger car field.

This combination of influences has already impressed on many truck makers the necessity of keeping more in the public eye, and incidentally more in the dealers' eyes. Before another year it will be astonishing if truck makers do not unite in some form of national demonstration, which will serve to bring their wares into the public eye in a forceful manner. A huge national truck show, accompanied by some form of outside demonstration, would succeed in this work. If not this, then, a great national demonstration or trial of some nature would serve the same mission. One thing is certain, namely, that any growing industry, such as the motor truck one, cannot afford to keep its light under a bushel. There is too much missionary work to be done for that. There are too many doubting Thomases to be convinced. United effort is needed. Instead of too much internal rivalry among makers, which saps activity, a more concentrated attack is needed on horse transportation. The field of possibility of the motor truck is so extensive that individual effort is not enough; the united attack of the industry is needed.

The Eight

NEW YORK'S fifteenth annual automobile show, which opens Saturday of this week, will have more wonders for the automobilist than several of the recent shows, and instead of the show losing interest as years go by the interest is annually increasing. One year ago few even vaguely imagined that stock eight-cylinder cars would be on the market in 1915, but already we have three different makes, and by the opening of the Chicago show one or two more may be announced, if the present pace is kept up. The eight-cylinder has proven a very easy manufacturing job, in fact, it is very closely associated with the four-cylinder, so that beginning its manufacture is not accompanied with those problems that accompanied the development of stock six-cylinder motors.

Up to this time the eight has not been taken up so actively by those concerns that have been building sixes, all announcements to date coming from those who have marketed only fours heretofore. This aspect of the eight would seem to indicate a possible dropping off of fours, but the opposite may prove the rule, because it will not be a difficult manufacturing job to build an eight and use one of the cylinder blocks for a small four. Viewed in this light it will not be surprising to see renewed activity in the small four, a movement which would without doubt point to the overcrowding of this market, which during the past fall has been one of the most active in the automobile field.

Motor Values

THAT we spend our years as a tale that is told, is almost demonstrated in the return this season to valve-in-the-head motors, a type of construction which is rapidly gaining in four-cylinder and six-cylinder construction, but which is not particularly adaptable to eight-cylinder design in that it makes too wide a motor.

Years ago the valve-in-the-head design demonstrated its greater power efficiency due to smaller combustion space and lower heat losses through the combustion chamber walls. In those days the engineer had not mastered the art of reducing motor noises, and the valve mechanism being on the cylinder head close to the top of the bonnet these noises were accentuated, the bonnet became a sounding board, and with the advent of quieter motors the valve-in-the-head design lost prestige.

Its revival came with the greater use of it in racing cars in Europe during the past 5 years. Europe was constantly reducing piston displacement and the only available means of increasing power seemed to lie in increasing the thermal efficiencies made possible by the head valve location. Thanks to the development of racing the problem of practically enclosing the valve mechanism was soon mastered, so that noise was eliminated. The difficulties of lubricating parts that previously were exposed to the dust were overcome, and by eliminating dirt and insuring lubrication, the previous problem of keeping the valve adjustments constant and quiet were largely overcome. Each year now sees more valve-in-the-head motors, and this movement will unquestionably continue, if not quite side tracked by the eight-cylinder.

The 1915 Will

TODAY we stand face to face with the opening of another year, another cycle of existence. The new year will have many surprises for us. Try as we can to decipher its hidden secrets, our final efforts end in failure. Too often we live too much in the future, too often our vague interpretations of coming events lead us to largely nullify our present efforts.

"Act, act in the living present" is good advice.

The future can best be taken advantage of by a steady consistent performance each day. It is unwise to frame all our activities of today by our estimate of the future. Were this so not a few concerns might decide to close shop until the war clouds have rolled away, but what a disorganized condition would that house find itself in, if it followed such a policy!

"Seedtime and harvest, summer and winter" have been with us since that Divine promise of their continuance was given, and this is a message to all, that our cycles of activities must be kept up, and that while exigencies may temporarily stampede business, and while war may upset temporarily many financial arrangements, still we must go forth to the day's work, with a firm heart, believing that our duty is to will that matters improve. We must go forth into the new year, not weighed down with pessimism, but buoyed up with that promise of centuries ago that business will continue, and that we as individuals owe a duty in sowing optimism rather than doubt.

Accessories Active

EACH year sees the accessory maker expanding his field, and becoming more and more a dominating influence in a greater number of cars. Thus for 1915 we find more makes of cars using motors built by concerns that specialize in building motors. The same is true of gearsets, of axles, and of steering gears. The specialty maker has been doing valiant service in the development of his product, and that he is quite in advance in various lines is well demonstrated by the speed with which eight-cylinder motors have been developed and perfected for marketing to the trade.

Some of the most interesting features of the show will be found in the accessory department, where over 250 different makers will exhibit. Novelty will be found in the older lines as well as the new concern brought into existence because of some recently acquired patent. Our magneto makers have progressed very much during the year, and although the magneto was considered a well-perfected device, yet the work of the past year has been along lines of simplification and efficiency. With them there has not been a feeling that the product is good enough, but rather one of keeping steadily improving.

Carbureter activity has been greatly stimulated during the past fall by the resurrection of fuel tests, together with the influx of smaller motors and the very general discussion on greater efficiency. New models have been brought out by old makers and new principles incorporated in not a few of them. The general movement to block casting has stimulated the horizontal type, which bolts directly to the casting, eliminating the manifold, and this type is coming rapidly.

Cord tires have made very material progress, and today more of the manufacturers are convinced of the greater mileage of these, the greater speeds possible with them, the greater fuel economy that accompanies their use, and the better hold on the road that they possess. Next year will doubtless see a wide increase in their use.

The adoption of vacuum-gravity fuel feed has been one of the accessory activities of the year, and its quick adoption has in many instances been due to the public efficiency tests that have been carried out.

1915 Specifications

THE AUTOMOBILE presents in this issue its annual specification tables of the leading passenger cars for 1915, these containing the details of approximately 115 different makes of cars. All, unfortunately, are not included due to bringing out later models, some of which will not be announced before the opening of the show.

These specifications give the most accurate clue to trends in design, when compared with those appearing on previous years. The many facts regarding American cars have been collected annually for the past 5 years and in this issue it has been possible to give trends extending over that period of time. It is only when we glance over a period of years that the exact current of the industry can be seen. From year to year detail trends not infrequently zig-zag, but these minor fluctuations are lost sight of in the general direction of the chart curve covering 5 or more years. Thus we find that wheelbases may shorten a fraction of an inch one year, but this is immaterial when the general increase of 4 other years is noticed; and by comparing the advent of the six-cylinder movement with the trends in wheelbase it can be regularly noticed how the invasion of the six into each price classification has resulted in 5 or 6 inches being added to the wheelbase. Comparisons of this nature over 5 years have most valuable lessons; in short, in them lies the great clue to the possible paths of tomorrow.

Handley Forms $1,000,000 Company

Mutual Motors Co. Plans To Manufacture Complete Cars for Marion and Imperial

INDIANAPOLIS, IND., Dec. 30—By the incorporation of the Mutual Motors Co. with $1,000,000 capital J. I. Handley, president and owner of the Marion Motor Co., re-enters the automobile industry as president and general manager of the Mutual Motors Co., which will be devoted entirely to the manufacture of automobiles in Jackson, Mich., where complete cars will be built for the Marion Motors Co., of Indianapolis, and also for the Imperial Automobile Co., of Jackson, Mich. The Mutual Motors Co. is to be solely a manufacturing organization and will in no wise be interested in the sale and distribution of either the Marion or Imperial cars which it will manufacture, but rather the Marion and Imperial companies will remain independent and complete within themselves for the sale and distribution of their respective cars.

The Mutual Motors Co. has already secured a plant consisting of a two-story building, 900 by 440 feet.

Of the $1,000,000 authorized, Mr. Handley says that $600,000 has already been contracted for. The directors of the newly formed Mutual Motors Co. are: B. M. DeLamater, president of the People's National Bank of Jackson, also president of the Jackson Cushion Spring Co.; W. S. Kessler, president Albion Malleable Iron Co., Albion, Mich.; W. R. Smith, treasurer and general manager of the Jackson Cushion Spring Co.; T. A. Campbell, treasurer and general manager of the Imperial Automobile Co.; J. I. Handley, president and owner of the Marion Motor Co.

Other prominent men who have already procured a stock interest in the new company are: A. Hirscheimer, president of the LaCrosse Plow Co. and the Batavian National Bank of LaCrosse; H. J. Hirscheimer, vice-president LaCrosse Implement Co., Minneapolis; B. F. Hamey, general manager LaCrosse Implement Co.; Winthrop Withington, president Sparks-Withington Co., Jackson, vice-president and general manager American Fork & Hoe Co.; H. S. Reynolds, vice-president People's National Bank, Jackson; T. E. Barkworth, ex-president Michigan Bar Assn.; F. E. Davis, general manager automobile department LaCrosse Plow Co.; George Campbell, sales manager Imperial Automobile Co.

Allegan Gets Blood Bros. Plant

ALLEGAN, MICH., Dec. 26—Efforts to have the Blood Bros. Machine Co., remove from Kalamazoo where they are now located to this city have ended successfully and contracts were signed to that effect. The amount of $50,000 which the Blood company asked that be raised by Allegan people has been over-subscribed, it is said. Just when the concern will locate here has not been ascertained, but when located here the company will arrange to bring out a small four-cylinder roadster and touring car next June or July.

Krit Car and Sales Cos. File Petition

DETROIT, MICH., Dec. 28—A voluntary petition in bankruptcy was filed today by the Krit Motor Car Co. and by the Krit Sales Co. The action was agreed upon at a meeting of the board of directors, December 21, which stated that the company is unable to pay its debts in full.

The liabilities of the Krit Motor Car Co., total $881,088.47; the assets total $622,533.27. Liabilities of the Krit Sales Co. are $234,305.63; assets total $256,814.70. Among the liabilities is $28.657.13 in deposits from nearly 175 dealers.

The Krit Motor Car Co. was organized in September, 1909, with a capital stock of $100,000, which was later increased to $500,000. Two years ago the company was in financial trouble but was reorganized. Last February the Krit Sales Co. was organized with a capital of $100,000 for the purpose of enabling the Krit Motor Car Co. to obtain materials and parts for car manufacture as well as meet its pay-roll. Several officers of the car company are also among those of the sales organization. Referee in Bankruptcy, Joslyn, has called a meeting of the creditors for January 18, to appoint a trustee.

Automobile Securities Quotations

NEW YORK CITY, Dec. 29—The stock market showed a slightly weaker tone during the past week than was the case the week before, most of the securities experiencing declines of a point or so, though a few showed gains of about the same magnitude. The only large increase was that by Ajax-Grieb common, which gained 10 points. The preferred dropped 1 point. Firestone common lost 2 points, General Motors, Goodrich, Kelly-Springfield and Maxwell were slightly off, as were Studebaker and U. S. Rubber, as compared with last week's figures. Goodyear common and preferred were 2 points higher, while Willys-Overland gained 1 point on the common and 2 points on the preferred.

Maxwell and Case Stocks Listed on Exchange

NEW YORK CITY, Dec. 24—The governing committee of the Stock Exchange has approved the listing applications of the following companies:

Maxwell Motor Co., Inc., $9,791,800 stock trust certificates for 7 per cent. cumulative first preferred stock, $7,457,900 stock trust certificates for 6 per cent. non-cumulative second preferred stock and $9,586,200 stock trust certificates for common stock.

The J. I. Case Threshing Machine Co., $6,816,700 extended stock trust certificates for preferred stock to 1918 "stamped."

Chandler Common Pays 17½% in 1914

CLEVELAND, O., Dec. 24—The Chandler Motor Car Co. has declared the regular quarterly dividend of 1 3-4 per cent. on its preferred and an extra dividend of 2 1-2 per cent. on its common stock. This makes 17 1-2 per cent. paid on the common stock in the calendar year 1914, and the company's surplus after the 1914 dividends is equivalent to more than the $225,000 par value of all common stock.

LONDON, ENGLAND, Dec. 26—Plans have been made for a limited reopening of the London stock exchange with no speculative business at the outset. A committee has been appointed to fix maximum prices in other securities outside the gilt-edge group, should occasion arise. Every one who wishes to be member of exchange must be a British subject.

Market Reports for the Week

NEW YORK CITY, Dec. 30—The usual changes occurred in the market reports this week. Electrolytic copper was lower, closing at $0.12 5-8 a pound. The tone of this market is weak. According to reports there will be a decrease of 10,000 tons in output in Russia and Spain in 1914. Tin fluctuated throughout the week and closed with no change. This metal was weaker this week with small sales. Lead was quiet and unchanged. Prices in the oils and lubricants markets continue steady with a fair demand. Trading in crude rubber continued quiet. Fine Up-River Para came down $0.01, closing at $0.75. The offerings in this rubber were light and the prices were in all instances apparently well maintained. Supplies of rubber in New York City continue light.

To Sell Lozier Property February 1

DETROIT, MICH., Dec. 29—*Special Telegram*—At the first meeting of creditors of the Lozier Motor Co. since the concern was declared bankrupt, the Detroit Trust Co., which has been acting as receiver, was elected trustee. Referee in Bankruptcy Lee E. Joslyn ordered that the property of the Lozier company be offered for sale, either as a whole or parcel about February 1 subject to confirmation by the court. A deposit of 10 per cent. but not more than $25,000 must be made by a bidder, and the bids are subject to the acceptance or rejection of the court.

Bearings Co. of America Succeeds Bretz Interests

NEW YORK CITY, Dec. 29—The Bearings Co. of America has been formed to succeed the J. S. Bretz Co., the Fichtel & Sachs Co. and the Star Ball Retainer Co., both of Lancaster, Pa. All three of the old companies were dissolved during 1914, the idea being to concentrate the entire manufacturing, warehousing, the shipping and service departments at Lancaster, and the entire sales department at 250 West Fifty-fourth street, this city.

No change has been made in the personnel. The company will continue to sell, produce and import F. & S. annular ball bearings, ball thrust bearings, Star ball retainers, German steel balls and Bowden wire mechanism.

Profit-Sharing by Detroit Companies

DETROIT, Mich., Dec. 28—The King Motor Car Co. will distribute at least 10 per cent. of its total profits for the year 1914 among all its employees in January. About 200 men and women will share in the profits, as was the case in January, 1914, when 10 per cent. of the profits made in 1913 were given all those connected with the company but who are not stockholders. The share of each employee is determined according to his annual salary.

Following a custom which was inaugurated several years ago, the Ford Motor Co. has distributed a part of its annual profits in the way of a Christmas present among 200 to 300 heads of departments, general foremen, factory heads, old employees not only with the plant here in Detroit, but with the various assembling plants, branches and foreign branches all over the world. The total amount is not disclosed, but it represented the output of about one-half the number of cars made in one day at the Ford plant, which would be from 800 to 1,000 cars.

The Federal Motor Truck Co. gave all its employees, 150 to 200, a Christmas present in the shape of a deposit in a savings bank, representing 10 per cent. of their wages for the year. The idea was rather novel and seemed to have been more appreciated by the employees than if checks or currency would have been given. The reason of the Federal company in having the money placed to the credit of each employee was to instill further the saving habit among them.

Rubber Industry Protests Embargo

Daily Cost to Manufacturing Interests Totals $250,000—No Improvement in Situation

NEW YORK CITY, Dec. 26—Representatives of large rubber manufacturing interests who have been conferring with representatives of the State Department in Washington and of the British Embassy with regard to the embargo which the British government placed upon shipments of crude rubber coming from Ceylon and the Federated Malay States in November last, state that they are unable to report substantial progress. The matter has been in negotiation with the authorities in Washington, with the British Consul in this city and with the British government in London for more than a month, but the latter, while not willing to raise the embargo entirely, is ready to permit rubber from British colonies and London to be shipped to America if our manufacturers will give satisfactory guarantees that neither raw material nor manufactured articles will be sent to Germany or Austria.

F. A. Seiberling, president of the Goodyear Tire & Rubber Co., Akron, O., on December 28 visited Washington and made representations to the United States government and the British embassy regarding Great Britain's action in placing tires and other rubber products on the contraband list. Mr. Seiberling saw President Wilson, in company with Senator Pomerene and Ex-Senator Charles Dick, of Ohio. On the same date the U. S. government forwarded to the British government a memorandum which, while not so officially designated, is in the nature of a protest against Great Britain's embargo and other restrictions upon American commerce.

Mr. Seiberling and B. G. Work, president of the B. F. Goodrich Co., Akron, O., and representing the Rubber Club of America, will go to London to lay a protest before the British government.

According to certain authorities, this embargo is costing the rubber industry about $250,000 a day, and has sent the price of plantation up to 90 cents a pound, against the normal price of 45 to 55 cents. Roughly speaking, this means the cutting off of over 50 per cent. of the normal supplies of crude rubber required by the industry in this country. Fine, up-river Para went up from 60 cents to 76 cents.

As a result of the war German chemists have been confronted with a number of important technical problems, chief among which are those of furnishing suitable substitutes for gasoline and rubber. No trouble has been found in finding a suitable substitute for gasoline, as benzol and alcohol, the former being a by-product of the manufacture of coke, the production amounting to about 160,000 tons a year. About 100,000 tons are available for fuel purposes. There is no shortage of alcohol for motor purposes.

But the problems arising from the shortage of rubber are much more difficult than those arising from the fuel situation. The importation of caoutchouc, India rubber, has been interrupted, and the synthetic production of this material was neglected before the war. Several satisfactory substitutes have been evolved by combining acetone and benzol products with caoutchouc. A certain supply of caoutchouc can be maintained by the manufacture of regenerated caoutchouc from scrap rubber.

The rubber problem in the United States has caused a syndicate in Akron to enter into contract with a number of ranch owners of Texas for the right to grow and gather the guayule shrub upon their renting several million acres of land. It is said to be the purpose of the syndicate to ship the guayule shrub to Akron where it will be manufactured into crude rubber. Marathon, Tex., has the only factory making crude rubber in the United States.

McGraw Tire Co. Offers $500,000 Stock

EAST PALESTINE, O., Dec. 26—The McGraw Tire & Rubber Co., through the Maynard H. Murch Co., Cleveland, O., has offered $500,000 in 7 per cent. preferred stock.

Net earnings of the company for the fiscal year ended November 30, 1914, were $594,136. This is about seventeen times the preferred dividend charges. In 1913 net earnings amounted to $285,558. The company has net tangible assets, exclusive of good will, patents, etc., of $1,353,670. It is capitalized at $500,000 common and $500,000 preferred.

Show to Open with 360 Exhibits

50,000 Square Feet More Space—Additional Exhibits Expected—500 Cars and Chassis on Display

NEW YORK CITY, Dec. 28—The fifteenth annual automobile show will open on Saturday, January 2, at 2 o'clock in the Grand Central Palace, this city. There will be 360 exhibits of automobiles, motorcycles and accessories distributed on the four lower floors. The exhibition will last 1 week, opening each day at 10 a. m. and closing at 10.30 p. m.

The first two floors will hold the automobile exhibits, with the six electric car exhibitors grouped on the second floor. The accessory exhibitors will be on floors three and four exclusively.

The National Automobile Chamber of Commerce anticipated the largest automobile show this city has ever held by enlarging the exhibit space by 50,000 additional square feet, as compared with a year ago, making the grand total of 150,000 square feet. There are, approximately, seventy-six makers of gasoline cars, there may be two or three more by opening hour; six makes of electrics; thirteen motorcycle makers, and about 284 makers of accessories and component parts for cars. It is certain that the above number of exhibitors will be materially increased at the eleventh hour, so that the total of 352 exhibitors at the show in 1914 will be equalled if not eclipsed. Last year a total of 492 different cars and chassis were displayed and it is expected that this figure will be slightly exceeded. Perhaps more than 500 vehicles will be on display.

Of the seventy-six makes of cars, fifty-nine are members of the N. A. C. C., Inc., and seventeen are outsiders, these non-members to date including Crawford, Davis, Durant, Enger, Grant, Herff-Brooks, Lexington-Howard, L. P. C., Owen, Patterson, Pilot, Remington, Scripps-Booth, Twombly, Trumbull, Malcolm and Gadabout. Not all N. A. C. C. members are exhibiting, several familiar faces of past years being missing, among these being noted Abbott, Austin, Great Western, Lozier, Marion, Pope-Hartford, Pullman, S. G. V., Speedwell and Staver, some of which have ceased manufacturing operations during the past year and others who are simply not exhibiting.

It is estimated by Manager S. A. Miles of the show that $1,000,000 will be spent in this city by those attending the show. According to his estimates, over 20,000 out-of-town visitors will attend, 95 per cent. of whom will stop at hotels.

Axle Makers Unite Against Kardo Co.

BOSTON, MASS., Dec. 30—That a combination among axle makers to fight the suit recently started by the Kardo Co., against the Salisbury Wheel & Axle Co., Jamestown, N. Y., is in process of formation was practically verified today. Frederick P. Fish, of the law firm of Fish, Richardson, Herrick & Neave, of this city, are preparing the case and conducting the investigation at the present time. This is the same firm that has undertaken the case for the National Automobile Chamber of Commerce, which is handling the suit of the Studebaker Co., against the Kardo interests.

Word comes from Detroit that the majority of the large axle manufacturers will unite to protect one another in this patent litigation, and although details of the work are not available, it is understood H. W. Alden, engineer of the Timken-Detroit Axle Co., is the moving spirit of the enterprise and that the majority of the axle manufacturers have agreed to unite in fighting the patents.

The Kardo patents refer to floating axle constructions and also certain front axle constructions in which the vertical pivot in the axle ends bears a relationship with the point on the ground on which the tire rests.

C. of C. Named in Windshield Suit

CLEVELAND, O., Dec. 26—Action was brought in the United States District Court Thursday, December 24, making the National Automobile Chamber of Commerce co-defendant in the suit for infringement brought by William B. Hanlon, James R. Wardrop and the Anderson Electric Car Co. against the Rauch & Lang Carriage Co.

Legal notice is served against the National Automobile Chamber of Commerce, its patent committee, officers and directors, excepting the Anderson Electric Car Co. It names Windsor White, of the White company, as one of the vice-presidents.

The complaint alleges that on February 16, 1914, they filed action against the Rauch & Lang Carriage Co. for alleged infringement of patent on shields for car windows issued to William B. Hanlon December 2, 1913.

The feature of the patent in suit is that it uses two panes of glass, forming the upper part of the windshield, one pane being in front of the other. The outer one can be swung outward and forward, forming a protector against snow and rain and affording a clear vision, while the inner glass remains vertical, making a complete windshield in conjunction with the single pane which constitutes the lower half. Both the panes in the upper portion are movable.

Ford Wins Suit to Protect Name

CHICAGO, ILL., Dec. 29—A final injunction has been issued by Judge Landis against Fred Buck, in business as the Barry Sales Co., in the suit brought by the Ford Motor Co. restraining the defendants from using the Ford name and trade mark in any way and from representing that any relation exists between them and the Detroit factory. The Ford company complained that the defendants had a Ford sign and trade mark on their building when they had no right to do so, the company not being a Ford dealer but buying cars from other dealers. The case was in the U. S. district court for the Northern district of Illinois, Eastern section.

Preliminary Injunction Denied in Horn Suit

NEW YORK CITY, Dec. 29—Judge Hand has denied the motion for a preliminary injunction made by Gottfried Piel and the G. Piel Co. in the suit against the Stewart-Warner Speedometer Corp. of New York and the Stewart-Warner Speedometer Corp. of Virginia involving alleged infringement of the Long hand horn patent No. 1,090,080. Judge Hand states, in his opinion:

"Whatever may be said of the patentability of the device, as disclosed, clearly it cannot be thought to cover the defendant's device if the claims are to remain valid. * * *"

Ritz Cycle Car Co. Sues for $50,000

NEW YORK CITY Dec. 28—The Ritz Cycle Car Co., of this city, has filed suit for $50,000 damages against the Driggs-Seabury Ordnance Corp., Sharon, Pa., alleging failure to carry out its part in a contract calling for the manufacture and delivery of 500 small cars to be known as the Ritz at the rate of 100 cars per month during June, July, August, September and October of this year. The Ritz company, in its bill of complaint, charges that the contract was entered into on April 8 and alleges that it deposited with the Driggs-Seabury corporation $5,000 in cash and two promissory notes for $2,500 each, payable 3 and 4 months, respectively, after the date of the contract. This money, it states, was to cover the cost of dies, jigs, tools, fixtures, etc., required for the manufacture of the Ritz cars.

The Ritz company alleges that the Driggs-Seabury corporation has furnished and is about to furnish cars called the Ritz, and made from the drawings, plans, etc., prepared by the Ritz company, to persons with whom the latter had contracts, and, moreover, that the price of these cars is lower than that which the Ritz company intended to ask. The concern claims damages to the extent of $50,000 and requests an accounting. It also asks for both preliminary and final injunctions against the Driggs-Seabury corporation using the name Ritz or making cars from the drawings, plans, etc., the Ritz company claims to have prepared. The bill of complaint concludes with the request that the Driggs-Seabury corporation bear the costs of the suit, which is brought in the U. S. district court for the Southern district of New York.

Prest-O-Lite Co. Wins Patent Injunction

LANSING, MICH., Dec. 21—An injunction against Roy O. Perry, doing business under the name of Haight Auto-Lite Co., South Washington avenue, has been granted to the Prest-O-Lite Co., Indianapolis, Ind., by Judge Tuttle of the United States District Court of Detroit. It is held that the local company infringes the patents of the Indianapolis concern.

Canadian Ford Profits $2,022,496

Surplus of $1,804,846 and $1,257,032 in Cash on Hand and in Bank—25,000 Cars Made

DETROIT, MICH., Dec. 24—During the fiscal year ending October 31, 1914, the Ford Motor Co. of Canada, Ltd., made a total profit of $2,022,496.06, or over 200 per cent. on its capital stock, which is $1,000,000. At the same date the concern has $1,804,846.30 surplus to its credit, and its account of cash on hand and in the bank showed a total of $1,257,032.35.

Thus ended the most successful business year the Canadian Ford company has had since the plant was started in Ford City just 10 years ago last August. The prospects for 1915 are declared to be very good, notwithstanding the war and the fact that a large percentage of the annual output is shipped to foreign countries.

The balance sheet shows the total value of the assets at $5,603,618.41, consisting of the following items: Cash on hand and in bank, $1,257,032.35; due from customers, $347,149.17; prepaid expenses such as gasoline, oil, insurance, stationery, lumber, $127,707.69; plant account, $2,358,034.03; store accounts $1,513,695.17.

The liabilities which total $5,603,618.41 consist of these items: Accounts payable, $284,621; accrued pay rolls and miscellaneous expenses, $64,207; dealers' contract deposits and miscelalneous credits, $116,679; contract rebates, $34,603.41; reserves, $276,166—consisting of $140,934 for depreciation and $130,101 for unearned profits; loss and gain, $2,022,496; surplus, $1,804,846, and capital stock, $1,000,000.

The report of the year shows that investments in buildings and building fixtures total $641,595 or $73,710 more than in 1913; real estate holdings are recorded with a value of $183,544 or an increase of $22,500 over last year; the value of the machinery equipment is placed at $590,415, or an increase of $120,923 over 1913.

The real estate value of the company outside of the plant in Ford City is $214,354 for Montreal which is an increase of $141,645 over last year; $199,279 for Toronto, which means an increase of $148,278, as compared with 1913.

Like the parent company in Detroit, the growth of the Canadian Ford company has been one of the most remarkable in the history of industrial enterprises. Probably no other concern in the Dominion has grown so rapidly to such a prominent position and into such a financially strong manufacturing enterprise.

In August, 1904, the organization of the Ford Motor Co. of Canada, Ltd., was effected, the capital stock being $125,000. The first cars were shipped in February, 1905, and the total output for 1905 was 114 cars, while total values of sales effected during the year was $110,000.

In 1906 only 101 cars were made, of which seventy-six went to foreign countries and only twenty-five into Canada. Additional machinery was installed that year and in 1907 the production totalled 327 cars, of which 236 were disposed of in Canada and ninety-one shipped abroad. The output in 1908 was 324 and nearly one-third—114—went to foreign lands. In 1909 the first of the now famous Model T was made and that year 486 cars were built, of which 364 remained in the country.

Sales Total Over $12,000,000

Beginning 1910 production in large quantities started and at the end of that year 1,200 cars had been made. In 1911 the output was doubled, while in 1912 the cars made totaled 6,500. The record for 1913 was more than doubled and in 1914, it is stated, about 25,000 were made and shipped. For 1915 the output schedule calls for 35,000 cars.

In 1905 there were sixteen employes on the pay roll. In 1914 there were nearly 1,200. The value of the sales, which in 1905 was $110,000, totaled over $12,000,000 in 1914.

Reports from Receiverships

BOSTON, MASS., Dec. 28—Judge Aldrich of the United States District Court has authorized the Massachusetts receivers of the Pope Mfg. Co. to join with the Connecticut receiver of the company in granting to the Maxwell Motor Co. an assignment of the contract of October 5, 1906, between the Pope Mfg. Co. and the Rubber Goods Mfg. Co., which contract insured to the Pope companies on all purchases of tires the lowest market prices.

The maximum total rebate was fixed at $250,000 in the contract. There now remains an unexpired credit of between $140,000 to $150,000 to the Pope company.

NEW YORK CITY, Dec. 24—The Overman Tire Co., 1853 Broadway, has filed schedules showing liabilities $54,054 and nominal assets $1,434,187, consisting of manufacturing and selling rights, $1,300,000; stock, $27,367; machinery in Passaic, $29,961; accounts, $29,837; automobiles, $3,000; fixtures, $3,279; cash in bank, $9,645; cash on hand, $111; notes, $847, and insurance, $409. The largest creditor is the Manhattan Rubber Mfg. Co., with $44,306.

DETROIT, MICH., Dec. 26—Referee in Bankruptcy Lee E. Joslyn has ordered that the property of the bankrupt Detroit Electric Appliance Co., Fort and Fourth streets, is to be sold at public auction by the Detroit Trust Co., trustee. The property, which consists of machinery, materials, supplies, tools, office fixtures and furniture, will be disposed of either in one lot or in parcel. The bankrupt concern made the Deaco starters.

DETROIT, MICH., Dec. 28—A trustee has been appointed for the S. & M. Motor Car Co. by Referee in Bankruptcy Lee E. Joslyn. The trustee reports $2,433.87 on hand for distribution among the creditors of the company. The final meeting of the creditors will be held at Room 205, 58 Lafayette avenue, Detroit, on January 5, 1915, 9.30 a. m.

DETROIT, MICH., Dec. 26—The personal property of the bankrupt Wahl Motor Co. was sold yesterday for $2,100 to A. C. Barley, of Streator, Ill. Referee in Bankruptcy Lee E. Joslyn appointed Harry Moultrop trustee. A first dividend of 3 per cent. was ordered paid to the creditors.

Burman Beats Oldfield in 50-Mile Race

LOS ANGELES, CAL., Dec. 27—*Special Telegram*—Bob Burman defeated Barney Oldfield today in the first of their series of 50-mile match races and in doing so he came very close to the half-century record, his time being 45:54, whereas Disbrow holds the mark at 45:32. Barney was 4 seconds behind Burman.

Burman drove his French Peugeot and Oldfield started in his Fiat Cyclone. On the first lap, however, the timing gears on the Fiat were stripped. Barney shifted to Earl Cooper's Stutz and the race was started over. His skill on the turns enabled him to hold Burman but on the twenty-eighth lap Bob picked up a nail which made a tire change necessary, which cost 17 seconds in which time Barney gained 1-2 mile. Burman caught him on the forty-eighth lap.

There were almost 20,000 spectators and the managament was forced to close the gates. The track was dusty after ten laps. Burman carried no mechanic while George Hill rode with Oldfield. The race was from a standing start.

LOS ANGELES, CAL., Dec. 21—Arthur Klein announced today that he would have an eight-cylinder King racer at Indianapolis for the next 500-mile race. The eight-cylinder racer is to weigh 1,750 pounds and have a piston displacement of 270 inches, according to Klein.

Venice 300-Mile Race March 17

LOS ANGELES, CAL., Dec. 17—Another great road race is practically assured for Southern California during the early months of the 1915 racing season. The Venice road race date has been set and a committee appointed to apply for the A. A. A. sanction.

March 17 is the date chosen by the Venice race boosters for the 300-mile event. A purse of $8,000 has been subscribed and this amount is to be raised to $10,000, according to members of the race committee.

There was talk of a Santa Monica race, but there were certain citizens of the seaside city who were opposed to a 1915 race. Mayor Dudly of Santa Monica had been informed by property owners along the famous course that the city would be enjoined should any attempt be made to hold a race.

LOS ANGELES, CAL., Dec. 24—Barney Oldfield is to be president of a corporation which will build a 1 1-4-mile board motor speedway. The plans call for two 1-4-mile straightaways with triple-radius turns. The grandstand, which is to be completed for the opening meet, is to seat 50,000, and with the infield space 100,000 can easily be accommodated.

It is Oldfield's intention to have the first race after the San Francisco events and before the drivers have to appear at Indianapolis. Oldfield will handle the American drivers.

Chalmers Has Block Cast, Valve-in-Head Six

DETROIT, MICH., Dec. 28—Today the Chalmers Motor Co. has given out the details of its model 32 new six-cylinder car to sell at $1,400 which is to be seen for the first time at the New York show. The motor is the most unusual feature of the new Chalmers in that it is a block cast type with the camshaft overhead and operating the valves which are also in the head. The whole mechanism is completely inclosed.

The engine has a bore of 3 1-8 inches and a stroke of 5 inches and over 40 horsepower is claimed for it. Ignition is by Atwater Kent apparatus in connection with the Gray & Davis two-unit system of cranking and lighting. Other specifications include multiple dry disk clutch, cantilever rear springs underslung from the axle, three-speed gearset on the rear axle, 120-inch wheelbase, 34 by 4 tires and frame following the lines of the body so as to give good support.

In connection with the motor construction, the cylinder head unit includes the valves and their cages and the camshaft assembly. When the head bolts are removed the whole thing comes off and the pistons are exposed. The drive for the camshaft is by spiral gear. A shaft runs transversely from the crankshaft to the right side of the cylinder block, where it connects through spiral gears with a shaft running vertically upward to drive the camshaft. The shafting is all inclosed. The ignition distributor is located on the top of this vertical shaft, while the oil pump is at the bottom. Inlet valves are of nickel steel and exhausts of tungsten steel.

Other motor features are the use of Rayfield carbureter on the left side connecting it to the block by a two-branch manifeld and combination splash and pressure feed oiling. The camshaft is hollow and carries oil direct to the valve mechanism. Special sectional piston rings are used, the flywheel is uninclosed and the starting unit connects to its teeth.

Drive is through inclosed shaft with the torsion tube bolted to the housing of the gearset. The axle is floating and has Timken bearings in the differential with Hyatts in the wheels, a combination used throughout the running gear. The brakes are 14 by 2 inches on rear wheel drums. The rear cantilever springs are 52 inches long with the main leaf of vanadium steel. The car has left drive and center control and the fuel tank is in the cowl. Only the five-passenger streamline touring car is offered. It is fully equipped.

Princess Car $495 with Disco Starter

DETROIT, MICH., Dec. 26—Beginning January 1, 1915, the two-passenger Princess car, made by the Princess Motor Car Co., will be equipped with the Disco electric starter and lighting system and will be fitted with nickel-plated trimmings. The price of the car will be $495, or an increase of $20 over the present price, which is without the electric starter and lighting system.

The Princess is a small car having a wheelbase of 92 inches and 44 inches tread. It has a four-cylinder I head block motor, 2 3-4 by 4. The carbureter is a Holley. The transmission is a Warner selective sliding set. There are three speeds forward. The front axle is tubular and the rear axle of the semi-floating type. Hyatt roller bearings are used throughout. The front springs are semi-elliptic and the rear are cantilever. Artillery wheels are used, having 28 by 3-inch non-skid tires.

The body is made of sheet metal with a sloping French hood and a gunboat rear deck. The road clearance is 10 inches. The equipment includes top with hood and side curtains, adjustable windshield, two gas headlights with generator tank, one oil tail light, tire holder, number bracket, electric horn and tools.

Briggs-Detroiter Eight-Cylinder $1,295

DETROIT, MICH., Dec. 28—The Briggs-Detroiter Co. has brought out an eight-cylinder model with a 2 3-4 by 4.5-inch motor and 112-inch wheelbase at $1,295. The cylinders are cast in two blocks, starting and lighting is by the Remy two-unit system and a dry-plate multiple disk clutch is used. Left drive and center control are used and the wheels are wood fitted with 34 by 4-inch tires, the rear pair being non-skids. The front axle is an I-beam and the rear floating with semi-elliptic springs at the front and platform-construction at the rear. A touring body is fitted and a sedan may be added. The standard color is Brewster green. The company states that it will not discontinue the manufacture of four-cylinder cars.

To Make Crown Prince Steel Wheel

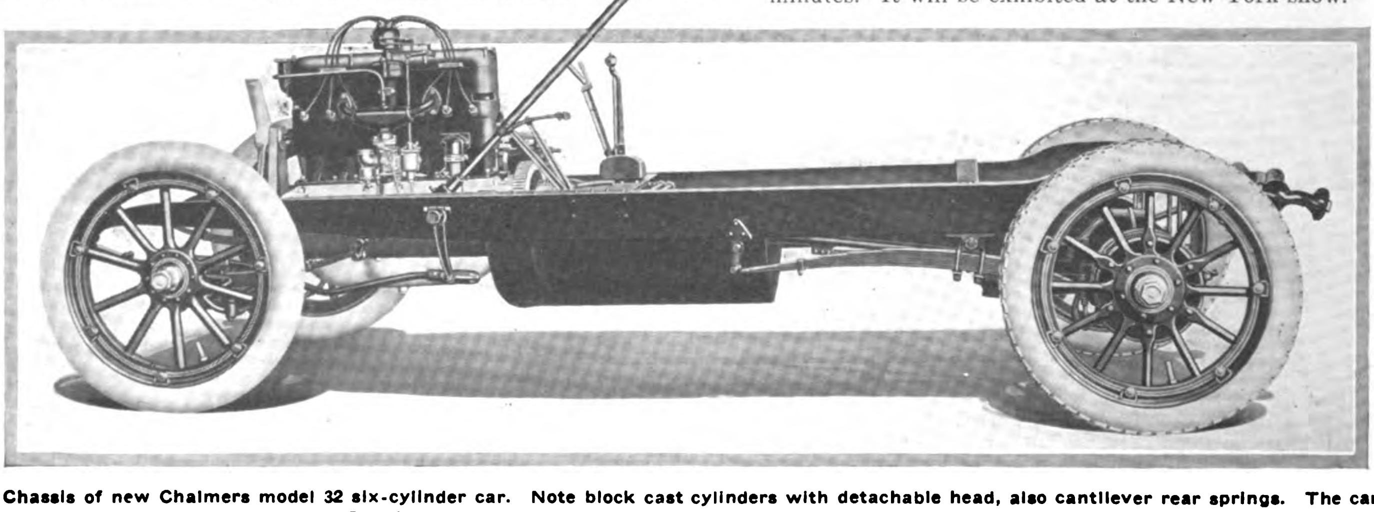
DETROIT, MICH., Dec. 28—The Crown Prince pressed steel wheel which is manufactured at Ohligs, Germany, and imported by Max Bachem, who introduced it to the American automobile trade at the New York show of a year ago, will be manufactured in this country under foreign patents by the Detroit Pressed Steel Co. The wheel is adaptable to both passenger cars and commercial vehicles.

Klaxon Announces New Price List

NEWARK, N. J., Dec. 28—On January 1 a new schedule of list prices will go into effect covering all models of Klaxon warning signals, manufactured by the Lovell-McConnell Mfg. Co., of this city. The Klaxon type L or S is now $20; the Klaxonet, $15; the Klaxet, $9; the Hand Klaxon, $7.50; the combination Klaxon with bulb horn, $30; the combination Klaxonet, $20.

Manzel Adds Ford Power Tire Pump

BUFFALO, N. Y., Dec. 29—The Manzel Bros. Co., this city, has brought out a new model engine-driven tire pump for Ford cars which sells for $7.50 complete with 12 feet of hose, pressure gauge and the necessary fittings. The pump is direct driven by gears from the crankshaft and is attached by removing the lower fan belt pulley and substituting for it a Manzel combination pulley and steel gear which are integral. The pump is attached to the side of the motor, the installation requiring about 45 minutes. No machine work is necessary. The pump will fully inflate a Ford tire in 1 1-2 minutes. It will be exhibited at the New York show.



Chassis of new Chalmers model 32 six-cylinder car. Note block cast cylinders with detachable head, also cantilever rear springs. The car has a 3 1-8 by 5-inch motor, two-unit electrical system, three-speed gearset and 34 by 4-inch tires

Factory Miscellany

MAXWELL Employing More Men—A report on business conditions from the Maxwell Motor Co., Detroit, Mich., shows that the company made big gains over last year and that its business and production has gained every month since the first of August. The company employed an average of 4,250 men daily for the months of August, September and October, 1913, with an average monthly payroll of $296,956.24. The recapitulation statement for the same months of this year shows a daily average of 5,818 men, with a monthly payroll of $427,-809.52, or an increased payroll of $130,-853.28 per month. The 30 days of November of this year make an interesting comparison, and shows that business conditions are actually better with the company since the war was declared in August. It employed 5,727 men daily during November of this year, as against 5,602 men in August of this year and 3,894 men in November of last year.

Piston Factory for Newark—The American Piston Ring Co., Newark, N. J., manufacturer of automobile pistons, will build a one-story, 75 by 150-foot plant at 378 Jelliff street.

Accessory Plant for Marion—E. C. Fox, of Marion, O., and J. W. Thomas, Cleveland, O., contemplate the construction of a factory in Marion for the manufacture of automobile accessories.

Federal Truck Gives Party—The Federal Motor Truck Co., Detroit, Mich., gave a Christmas party to all its factory and office employees, the feature of which was the presenting to each of them of 10 per cent. of his wages.

Federal Rubber's New Addition—The Federal Rubber Mfg. Co., Cudahy, Milwaukee County, Wis., is having plans prepared for a factory addition, to be 44 by 124 feet in size, 2 stories high, of fireproof construction. The addition is part of the $500,000 improvement scheme instituted about July 1 of this year. The capacity of the big tire works is to be more than doubled within a year's time.

Hastings Concern Making Shock Absorbers—The Bar-Bar Mfg. Co., Hastings, Mich., has begun the manufacture of shock absorbers and pilots for motor cars. The company has offices in Grand Rapids, Mich. Edward M. Barnes, of Hastings, is president of the company, and L. W. Barnhart, of Grand Rapids, is secretary and treasurer. Territory for the company's products is being taken rapidly.

Triple Action Spring Addition Built—The Triple Action Spring Co., Chicago, Ill., recently completed its new addition, 130 by 135 feet, devoted exclusively to the repair of automobile springs and the installation of Johnson shock absorbers. Forty-two men are employed in the shop and there is a payroll of seventy-five, which includes salesmen on the road. The company recently announced a special Johnson shock absorber for Dodge cars.

Peninsular Plant Sale Jan. 7—The plant and equipment of the bankrupt Peninsular Steel Castings Co., Iron and Wight streets, Detroit, Mich., will be offered for sale at public auction at 10 a. m. January 7, 1915. The property occupies a plot of ground 371 by 100 feet. The foundry building is 50 by 250 feet, and is equipped with machinery, tools and supplies, and could be well re-operated at once. The Security Trust Co., trustee, will furnish full particulars.

Goodyear Shows Sales Increases.—Figures showing the tire production of the Goodyear Tire and Rubber Co., Akron, O., for the last 6 years have recently been compiled, showing comparison of productions beginning with 1909. In that year Goodyear made and sold 102,669 tires; in 1910 the figures were 207,442; in 1911, 332,458; in 1913, 1,132,869, and in 1914 these figures were topped by a production of 1,478,396. This accounts only for the pneumatic tire produnction of the company.

24-Hour Schedule for Kissel—The truck shops of the Kissel Motor Car Co., Hartford, Wis., will maintain a 24-hour schedule for at least 30 days more to insure a quick production of the war orders placed recently. The company also has booked a large order for taxicabs from Los Angeles. Not before in the history of the Kissel shops has it been necessary to work on Christmas Day, or even during the holiday period. In former years the week has been used for inventory and overhauling, but this year operations are not only uninterrupted, but on a double-time schedule.

The Week in  the Industry

Motor Men in New Roles

Brown Bros. Manager Arrives in N. Y.—B. R. Banks, manager of the motor department of Brown Bros., Ltd., London, arrived in New York City on the Lusitania, December 22. His address will be at the Oliver Bros.' Purchasing Co., 71 Murray street, that city, where he will make appointments with manufacturers of American automobile accessories, with a view to their sale in Europe. Brown Bros., Ltd., is one of the largest jobbers in the United Kingdom, and already has the sole representation of the Raybestos brake lining, Gabriel horns and snubbers, Gleason Peters pumps, Edmunds & Jones lamps and New-Departure cycle sundries.

Donohue N. Y. Federation Secretary—G. C. Donohue has been named secretary of the New York State Motor Federation.

Lee Oldfield Heads Repair Dept.—Lee Oldfield, a race driver, has taken charge of the repair department of the Minnesota Automobile Laundry and Service Garage, Minneapolis.

Levey Joins Auto Parts Co.—Wm. B. Levey, formerly purchasing agent of the Borland-Grannis Co. and later of the American Electric Car Company is now purchasing agent of the Auto Parts Co., Chicago, Ill.

McNulty Saxon Representative — The Saxon Motor Co., Detroit, Mich., has appointed C. L. McNulty southern district representative. Mr. McNulty was for several years a district representative of the Studebaker Corporation.

New Oldsmobile Appointments—The Olds Motor Works, Lansing, Mich., recently appointed J. M. Otero as its representative for the island of Cuba, with a location on Paseo de Marti, at Havana. It also appointed Sojo & Co. agent for the Porto Rican territory.

Thompson Heads Morse Chain Branch—F. C. Thompson, formerly assistant chief engineer of the Lozier Motor Co., Detroit, Mich., has been appointed manager of the Detroit branch of the Morse Chain Co., Ithaca, N. Y., which has been opened in the Dime Savings Bank Building, Detroit.

Studebaker Promotions — Vice-President Benson, of The Studebaker Corp., Detroit, Mich., has appointed H. T. Myers manager of the department of delivery car sales. G. N. Jordon, traveling representative, succeeds Mr. Myers as manager of the corporation's Boston branch.

Finch Joins Standard Truck—E. B. Finch, who has been connected with the Packard Motor Car Co. and the Chalmers Motor Co., in their executive departments, has been appointed general sales manager of the Standard Motor Truck Co., Detroit, Mich. Mr. Finch will also be first assistant to President Albert Fisher.

Bayliss Cadillac Manager—J. E. Bayliss has been appointed Western district manager for the Cadillac Motor Car Co., Seattle, Wash., succeeding A. E. Landman, who resigned to join partnership with Don Lee, Cadillac distributor in California. Mr. Bayliss formerly was representative of the Packard Motor Car Co. and has been identified with the motor industry since its inception.

—

Garage and Dealers' Field

Benz Opens N. Y. Service Dept.—The Benz Automobile Sales Corp., New York City, importer of Benz cars and local distributors of Kissel cars, has opened a complete service department on West 55th street.

Flanders Electric Opens in Detroit—Salesrooms have been opened at 270 East Jefferson avenue, Detroit, Mich., by the Flanders Electric, Inc., Pontiac, Mich., manufacturers of the Flanders electric cars.

K. P. Headquarters in N. Y. City—The K. P. Foot Rest Heater Co., which formerly had its headquarters in Boston, Mass., has established its main office and New York distributing station at 250 West 54th street, New York City.

J-M Factory Branch in N. Y. City—The J-M Shock Absorber Co. has opened a direct factory branch at 250 West 54th street, this city. Edward Knauss, who was formerly Boston distributor for the J-M company is in charge of the local factory branch.

Takes Minneapolis Gibney Agency—The Northwestern Tire Co., Minneapolis, F. J. Kerner, manager, has taken over the northwestern agency for the Gibney solid tire, made in Philadelphia. This is the first time the Gibney has ever been handled in the northwest.

New McGraw Factory Branch—The McGraw Tire & Rubber Co., of East Palestine, O., maker of the Imperial, Pullman and Congress tires, and the McGraw solid tires, has opened a branch in Boston, Mass., at 667 Boylston street, with W. G. Page as manager.

Handling Century Starter—G. M. Weatherbee and C. A. Orr, formerly of the Hollander Motor Car Co., Boston, Mass., agent for the Cartercar, have formed a company to handle the Century starter for Ford cars with salesrooms at 29 Cambria street. Their territory includes Maine, Massachusetts and Rhode Island.

New Electric Garage for Detroit—The Indian Village Garage has been opened at 1524 Jefferson avenue, Detroit, Mich., by A. H. Dorsey, until recently manager of the local branch of the Anderson Electric Car Co. The garage has been built to take care of seventy-five electric vehicles and a small number of gasoline cars. The entire floor of 75 by 200 feet is free from posts.

Studebaker Buyers Receive Long Trips—An automobile dealer in the State of Washington has offered to a club of five customers a free trip from the Northwest to Detroit. The maker of the offer is Henry J. Laymance, Studebaker dealer at Waterville, Wash., who has advertised publicly that within 60 days from date of his advertisement all persons purchasing Studebakers will be given the free trip.

Secure Philadelphia Disco Agency—Carlile and Doughty, electrical and mechanical engineers, formerly of 406 South 8th street, Philadelphia, Pa., are the newest acquisitions to Automobile Row, now occupying 846 North Broad street, and have secured the agency for the Disco electric starting and lighting system for Ford cars.

Purchases Property—The Seaman-Sivyer Co., Milwaukee, Wis., a large independent oil and grease interest, has purchased the Phelps property at 249-251 Lake street, part of which it has occupied since its organization in August, 1913, and will occupy the entire building. Charles H. Seaman is president and Howard M. Sivyer vice-president of the company.

Palmyra Agent to Enlarge—Otto E. Scherer, agent for the Buick at Palmyra, Wis., and owner of one of the largest garage businesses in southern Wisconsin, will expend from $15,000 to $20,000 during the first half of 1915 in enlarging his buildings. When the improvements are completed, Mr. Scherer will have a building devoted exclusively to display and repair space and another for dead and live storage, washing, etc.

Last of Vermont Toll Road—The famous Peru turnpike in Vermont, one of the very few remaining toll roads in the East, will soon be abolished as the state has decided to either take it over by purchase from its owners or by right of eminent domain. It lies in the towns of Windham, Londonderry and Peru. The agitation for abolishing it began with motorists, who did not like to be paying toll every time they happened to pass that way.

Buick's Big Pacific Coast Shipment—Seattle will be the terminus of the first trainload of automobiles to come to the Pacific Coast in 1915, orders having been placed with the Buick Motor Co. for 200 pleasure and commercial models by the Northwest Buick Co., Seattle. The machines will be shipped in forty freight cars, and left Flint, Mich., on Christmas Day. They are coming in a special train, and the freight charges alone amount to $18,000, while the entire shipment is valued at $250,000. The machines are for distribution in Washington and Oregon.

Wis. Farmers After Insurance Business—Wisconsin farmers' mutual insurance companies are out to capture a share of the motor car underwriting business now controlled by stock companies. In the calls for annual meetings of more than fifty of the leading farmers' mutuals, it is stated that the question of authorizing the boards of directors to insure motor cars will be the most important proposition for consideration. The proposition grows out of the enormous number of cars now in the hands of farmers, who demand the low rate of insurance on their machines that is provided by the mutuals on their other farm property, including machinery.

The AUTOMOBILE

BRISCOE

Today the Briscoe is the car of big demand, as we can readily prove to you.

The BRISCOE is the car that the medium sized car buyer looks up to with a hopeful prospect of possession.

Perhaps he is the owner of some good small car, but wants a more ambitious one for the coming season. For some time he has felt that he ought to be able to get a lot more value—more high grade features, more smartness, better riding quality; in a word, *more car* for his $1000 or less; in fact—a BRISCOE.

On the other hand, a BRISCOE is pre-eminently the car that is going to attract the buyer accustomed to a big and more expensive car. Such a man needs mighty little saleswork. He is motor-wise, used to quick decisions on important matters, and will sell himself—if given a chance to look a BRISCOE over.

It is the converging of these two different public demands that makes the BRISCOE, at $785, THE CAR OF BIG DEMAND—*the ideal car for every Owner-Driver.*

Are you likely to do better than by handling the car that pleases one large class by its supreme value, and another large class by the very moderate figure at which it is offered?

(Better get in touch with us AT ONCE.)

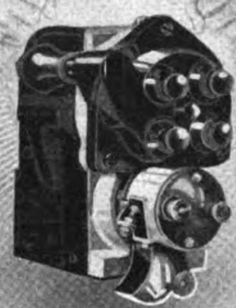
SPLITDORF

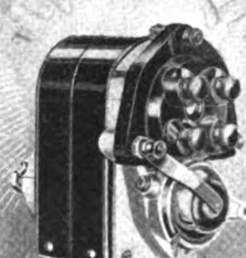
MODEL EU4-2
HIGH TENSION
MAGNETO



DIXIE
TYPE

SPLITDORF IGNITION devices for the 1915 season include several new types of magnetos of the high-tension variety. These have been designed to meet the clamor of automobile engineers for even more effective units for the popular demand.

Model EU4-2 is a big brother to the highly successful model EU4, being more powerful with its double magnets, and made for 4-cylinder motors developing as high as 40 horsepower. As standard equipment on 1915 *Overland* cars, among other makes of automobiles, the efficiency of the EU4-2 is "hall-marked" in view of the severe tests to which many thousands have been subjected.



MODEL EU4
HIGH TENSION
MAGNETO

Two new types of high tension magnetos, constructed particularly for easy starting without the use of battery, auxiliary coils or any external devices, are the DIXIE and the CUNNINGHAM.

The DIXIE TYPE is distinctly *new* and contains many interesting and valuable features—platinum points external to the main breaker-box—no wire on any of the revolving parts—field coil housed in the arch of the magneto—with timing lever at retard or advance the spark is of the same strength for any given speed—minimum loss of energy, etc. In the construction of the CUNNINGHAM there is practically no difference in the strength of the spark when the break is in advanced or retarded position, the speed remaining the same. By its construction an advance of 70° is obtained which is essential for long-stroke slow-speed 6-cylinder engines.

Operating slower than any engine will turn over on its own power and well below the limit for cranking speed, **an equipment of either the DIXIE TYPE or the CUNNINGHAM overcomes every excuse for having batteries around the car for ignition purposes. All that is necessary with either, is a simple switch for shorting the magneto when stopping.**

LBA Willard STORAGE BATTERY LBA

Anybody Can Make a Grid, but—

It takes experience and knowledge of a high order to make a thoroughly satisfactory storage battery plate.

With twenty kinds of lead oxides and twenty different ways of mixing them, there is an unlimited number of ways of going wrong.

Eternal vigilance is the prime factor—and every operation in the Willard plant is followed by inspection. Every pound of metallic lead has to be up to the Willard standard. Every grid is inspected when it comes from the mold. Samples of every keg of oxide go to the laboratory for inspection and testing. When the oxides are mixed they are tested. When the plate is pasted it is inspected, and again after it is dried. While the plates are "forming" the temperature and specific gravity of the electrolyte is under constant inspection and readings of the terminal voltage taken hourly.

Every batch of plates is subjected to laboratory test, and so is every lot of completed batteries.

Inspection is not the only reason that 85 per cent. of all makers of electrically equipped cars specify Willard Batteries, but is one of the big reasons for their uniformly good service and long life.

HOUPERT QUALITY IN A FORD MOTOR

Does your motor smoke? Do you want to increase your power? Do your pistons slap? Do you really want to bring your motor up to the high standard of the most expensive cars?

$25.00 Let Us Regrind Your Cylinders $25.00

and fit new pistons, rings, wrist pins and bushings.

We have the price to interest you and have maintained our quality throughout.

We would never have attempted to do this work if we could not offer you something superior to that obtainable elsewhere. Our whole aim in design and workmanship has been to deliver a product of quality with the working parts as light as is consistent with strength and durability and at a price within the means of the most economical Ford owner.

Don't experiment. Send your cylinders to us and be safe.

See us at Booth D142A at New York Automobile Show

HOUPERT MACHINE COMPANY

351 West 52nd Street **New York, N. Y.**

BUILD YOUR OWN CAR

Here is a new idea—an unusual opportunity for any man who is mechanically inclined to build his own car. You can buy the individual parts such as the motor, transmission, front and rear axles, steering gears, fenders, wheels, bodies, etc., from us at such ridiculously low prices that you can assemble them yourself and save 75 per cent. in the usual cost of a motor car.

We have one of the largest stocks of automobile parts and accessories in the United States and because of our enormous buying power are able to purchase supplies at one-third cost of manufacture.

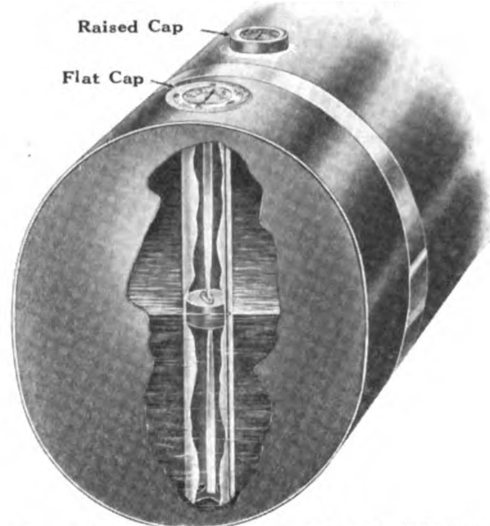
Let us quote you on your season's requirements for gasoline gauges. The following describes some of our types.

Pfahl Gauge
Style A

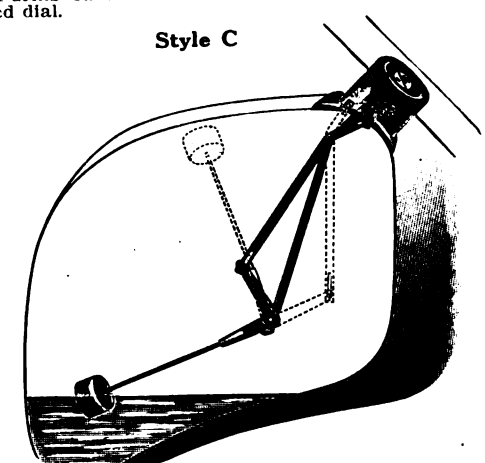


The style A Pfahl Gauge is made in different lengths, and can be used on any shape tank, round, oval or square, common gravity or where pressure is used.
Guaranteed pressure tight.
Easily attached.
Nothing to get out of order.
Can be installed on angle if desired.
Furnished with either silver plated or porcelain enameled dial.

Pfahl Filler Hole Gauge—Style F

Takes place of the filler cap.
Saves the cost of filler cap and flange.
Furnished with flange.
Knurled or octagon cap.
Built of heavy material that will stand the knocks
Furnished with either silver plated or porcelain enameled dial.

Style C



Made to fit any type of cowl tank.
Can be placed in many positions.
Held in position with cap and flange.
Can be removed from tank by removing cap.
Registers "Empty, ¼, ½, ¾, Full."

Pfahl Gauge—Style D

The style D Pfahl Gauge can be used on a round, oval, square or cowl tank, and can be attached in many positions.
Makes a very neat Indicator that will do the work.
Registers "Empty, ¼, ½, ¾, Full."
Write us for booklet and send blue print of Tank for quotations.

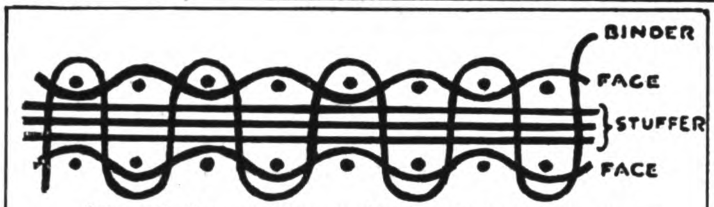
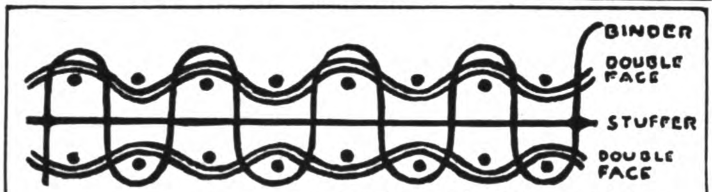
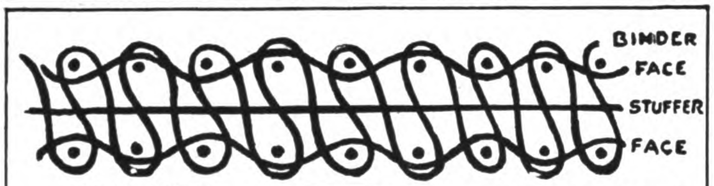
RAYBESTOS is—and always has been—made of the highest
uality of long fibre asbestos spun in the form of yarn around
vire.



One of the earlier methods of weaving brake lining.



A later stage in the development of brake lining fabric.



Illustrating the trend towards compact weaving.

The diagrams above show some of the methods used, since
scarded by us, in the development work of which RAY-
ESTOS is the result.

Special looms built to our own design now weave the fabric
e have trade-marked RAYBESTOS. So far competition has
en unable to copy it.

Ray

The PRODUCT of Bl

Sold by nearly every mobiles or automobile

You will know it by its silvered edge on every foot of it, distinguishes RAY

RAYBESTOS is the product of brake specialists

Our first activity as manufacturers was in the design, development and production of automobile brakes and brake mechanism.

During our whole business career we never have been guilty of producing a brake mechanism which our experience told us was not what it should be.

This same thoroughness is characteristic of our brake lining business. We never have taken a short cut to fortune if it involved the slightest chance of sacrificing the quality of our product.

No other concern in this country making brake linings has ever designed or produced brakes or brake mechanisms, and their knowledge of the problem they are undertaking to solve in the production of brake lining is not founded on nearly so practical a basis as that which underlies the design, development and manufacture of RAYBESTOS.

For this reason you should insist on RAYBESTOS.

Raybestos is the Pro

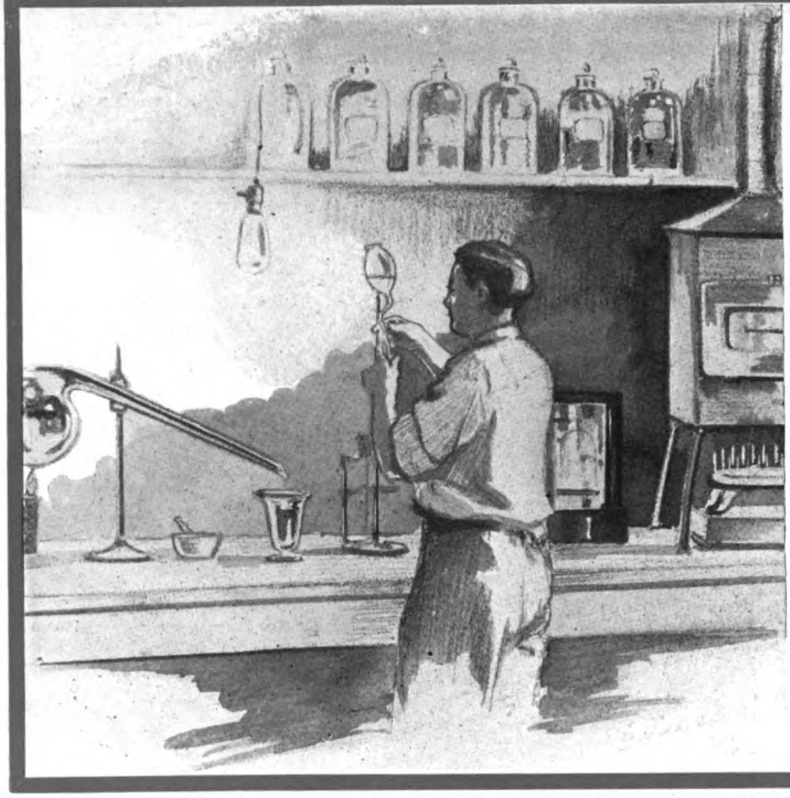
estos

AKE SPECIALISTS

leading dealer in auto- supplies.

s. This, and our trade-mark stamped BESTOS from the ordinary kind

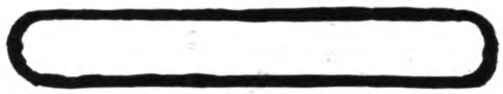


Successive stages of treatment which led up to the thorough impregnation of RAYBESTOS with our famous heat and wear resisting compound.

The efficiency of RAYBESTOS as a brake lining is beyond question

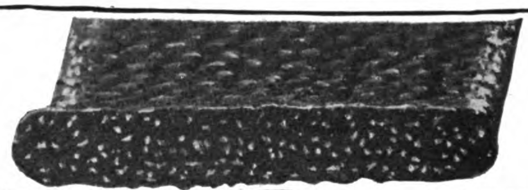
The most unfair competition cannot find a single weakness in it. Every strand in RAYBESTOS is woven and interlocked, one with another, into a homogeneous fabric of great tensile strength and solidity. With our improved machinery we attain a remarkably even thickness, which insures the uniformity of grip so necessary to the successful operation of automobile brake mechanism.

The most severe test any brake lining can get comes with its use on Motor Fire Apparatus. Fire Engines, Ladders, Chemicals, Hose Wagons, Patrols, etc., average in weight as much as the ordinary truck and far more than the heavy types of pleasure cars. They travel at a speed higher than ordinarily is attained by either trucks or pleasure cars. Fast runs with quick application of brakes for turning street corners and stopping are characteristic of their every-day usage. It is significant that nine out of ten motor fire vehicles of one kind or another in the United States are equipped with RAYBESTOS. This service is extraordinary, but there is no detail of an automobile which should be provided with any greater factor of safety than the brake mechanisms. No brake is any better than its lining.



First or surface treatment discarded by us years ago.

Partial impregnation—one stage in the effort to attain complete impregnation—discarded by us when the result shown below was accomplished.



Thorough impregnation photograph from the goods.

duct of Brake Specialists

RAYBESTOS fails to last one full year the time it is placed on the car, we will This Guarantee applies to all types and trucks.

The chemical treatment of RAYBESTOS is the really important factor which enables us to guarantee unqualified service from RAYBESTOS for one full year from the date it is put on the car.

How to Get the Bulk of the Brake Lining Business

To Dealers:

Sell the Brake Lining you would buy yourself.

If you follow this plan you will build up a better business and make more money in the end.

Look at it from your customers' standpoint. They know that the quality of RAYBESTOS is supreme. They know that its service is superior to that of any other brake lining. They know that it is backed by the most comprehensive guarantee ever given any brake lining.

These factors are more potent in swinging the bulk of the brake lining business to you than any other consideration.

Getting the benefit of the prestige, quality and service of RAYBESTOS to help build up your business is worth far more to you than a little longer discount on some other brand of brake lining. Longer discounts are aimed to attract you.

Your customers do not benefit.

You cannot give them any better quality — nor more attractive prices. Service in a brake lining is what they want. Service and a cut price never yet went hand in hand. The quality—the prestige—and our business-like methods of distributing RAYBESTOS constitute too much of an asset to you for you to be tempted by smart selling methods.

RAYBESTOS discounts are fixed—the same to each and every dealer. We believe in a square deal for everybody and we treat everybody exactly alike.

Quality is put into RAYBESTOS to insure service. The service of RAYBESTOS is definitely guaranteed. In every big city in this country there is a good, reliable concern which carries a complete stock of RAYBESTOS, ready to supply your needs on telephoned, telegraphed or written order. Any one of these concerns will quote our standard discounts to the trade—their discounts are the same as we would quote you direct. Their nearness to you, and their ability to make immediate deliveries of either large or small quantities makes it unnecessary for you to carry more than an easily handled stock for your immediate requirements.

METZ "25"

The Quality Car

This new METZ Touring Model is a winning proposition for enterprising dealers. It is a strictly high class car, deserving of your fullest confidence and recommendation, its attractive price being by no means its chief "talking point."

It is impressively complete and up-to-date, from its wire wheels and electric starter to its one-man top and electric lights. Wonderfully easy riding, clean-cut in design, luxuriously finished, and so simple in operation and reliable in performance that a woman can safely drive it.

We have planned and are developing an elaborate publicity campaign designed specially to help our dealers. We want representation in your territory. Write for particulars and new catalog "J."

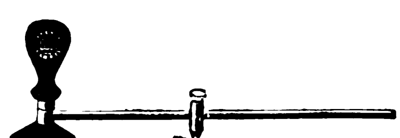
METZ COMPANY **WALTHAM, MASS.**

THIS "RED DEVIL" WILL CUT CIRCLES

It's the only practical glass cutter ever made for cutting full circles, half circles, or curves in any kind of glass—No. 263 "Red Devil" glass cutter. Useful for repairing headlights, etc. Has graduated rod marked to 16ths of an inch.

Sent postpaid for $1.25.

"RED DEVIL" CIRCULAR GLASS CUTTER No. 033



Cuts curves and circles with accuracy. To be had from your dealer or postpaid for 50 cents.

Send for booklet of Red Devil Tools.

172 Chambers Street, New York City

Troy Trailers

Double the Value of Your Truck

Keep your expenses where they are, but double your deliveries by hitching a Troy Trailer to your motor truck. That divides your costs and multiplies your capacity. Stop carrying and start hauling. Capitalize the draw-bar pull of your truck. Make one truck do the work of two. Every truck can pull more than it can carry if it has the right type of Trailer. Troy Trailers are proved by performance. Write for new book 4A.

The Troy Wagon Works Company
Troy, Miami County, Ohio

New York 50 Church St. | Detroit 319 Hammond Bldg. | Washington, D. C. 505 Riggs Building

M. A. Newmark & Co., Los Angeles, Cal., made total deliveries of 20 to 25 tons a day with a five-ton truck. The use of a Troy Trailer raised their deliveries to 50 tons daily and divided the cost per ton.

Sells on Sight to Ford Owners

Simple, Permanent and Efficient

The Improved Colstad Power Ford Tire Pump is the result of over three years of experimental and development work.

The Colstad always has been the simplest and most reliable Ford Power Tire Pump ever produced and now with its positive silent chain drive it is absolutely efficient to inflate regular or oversize Ford tires to the desired pressure in two or three moments. The pump cannot slip or fail in operation.

The Colstad is the original Ford Power Tire Pump.

Made in a thoroughly workman like manner and fully guaranteed. : :

Complete and Easy to Install

The Improved Colstad Power Ford Tire Pump Equipment consists of the Pump, Hose, Fan, Silent Chain Drive Mechanism—all for $10.

We furnish this equipment complete to insure easy installation. Hammer, screw driver and wrench are all the tools required to equip a Ford.

None but a chain drive is effective to drive a pump. We have experimented with and discarded belt and split gear drives.

Its installation is a benefit to the car as well as to its owners. : : : : :

SPECIALTY SALES COMPANY, **Sole Distributors 2 PARK PLACE, BOSTON, MASS.**

$695.00 SPHINX

112-In. Wheelbase Electrically Started and Lighted

Lightness, with strength and dependability—this is the SPHINX Car, in a few words.

This 112-in. wheelbase car with 4-cylinder monobloc motor, delivering 28 H.P., and with full standard equipment, handsome streamline body of excellent design and finish and easy riding cantilever springs, is pre-eminently the up-to-date light car for the average American family. It represents the point of arrival—the latest and most satisfactory result—in the transition from the big-car type to the popular-price car of full equipment and fine appearance.

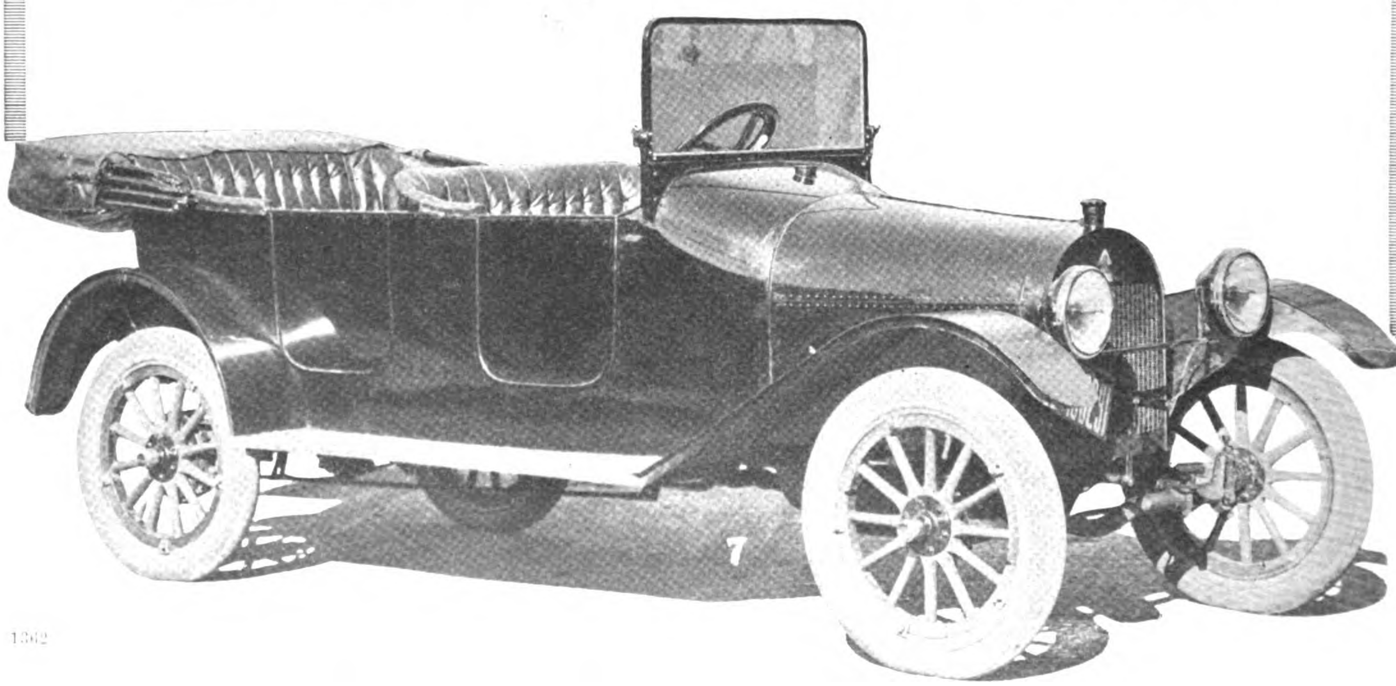
We say most emphatically and without equivocation that the SPHINX Light "Four" is the car with the largest selling possibilities to-day.

To clinch the matter and make it superlatively attractive to dealers we have a money-making proposition for SPHINX agents, carefully designed to move the cars into the possession of the great waiting public.

If you wish to embrace the opportunity of seeing this most remarkable car, if you want to secure your district rights, write or telegraph us immediately.

Will be on exhibition at 1692 Broadway, N. Y., from January 2d to 9th, 1915—and Greer Bldg., Chicago, January 23d to 30th, 1915.

SPHINX MOTOR CAR COMPANY, York, Pa., U. S. A.



OWEN

OM

MAGNETIC

"Thousand Speeds"

The Owen MAGNETIC

No other car on earth holds any comparison whatever with the OWEN MAGNETIC for supreme flexibility.

There are two things you should know about the wonderful OWEN MAGNETIC CAR—

FIRST:—The OWEN MAGNETIC comes from an experienced and authoritative source. This electric system was invented by Mr. J. B. Entz, whose inventive ability has placed his name in the list of America's greatest inventors. He made the first electric dynamos for the United States Navy and was Chief Electrical and Designing Engineer for the Edison Machine Company, afterwards the General Electric. He is also the inventor of the highly successful Entz Electric Starter. Mr. R. M. Owen of the OWEN MAGNETIC has for many years been well-known in the industry. Until recently he was Vice-President of the Reo Motor Car Company. So the men behind the OWEN MAGNETIC are practical, experienced and successful. When such men commit themselves to a device after years of tests, there can be no reasonable question about it.

SECOND:—The OWEN MAGNETIC is not an experiment, but is a public presentation of the success of this system throughout the past ten years. Many discriminating motorists are now driving these wonderful cars. One car alone has been operated for 150,000 miles. For years these cars equipped with this electric system have run side by side with similar cars with gear transmission through all conceivable driving conditions, over mountains, across states, over clay and through sand, and the OWEN MAGNETIC has proved itself victor every time. For economy this system has proved itself a little better than the gear set and for hill-climbing considerably better. So, the OWEN MAGNETIC comes in the form of a big public announcement of tremendous, all-important interest to those who keep abreast of motor car progress and who appreciate automobile evolution. This year the OWEN MAGNETIC will have a degree of exclusiveness. We shall build only a limited number of cars—practically custom made—of the highest quality throughout. But this Magnetic Transmission is bound to shortly become as common as self starters. Once its attractions become known, a high-grade car can't be marketed without it.

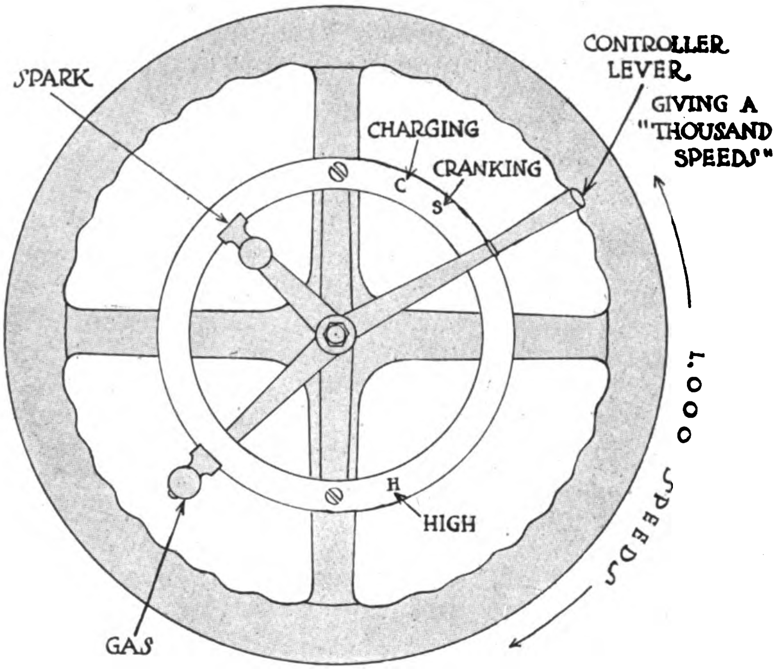
3-Passenger Roadster, $3750 } **F.O.B.**
7-Passenger Touring Car, $3750 } **New York**

The only American car with three individual brakes or brake-systems, which, if necessary can all be actuated at the SAME time.

The additional third brake is an electric-magnetic one, which is put into action, by simply moving the control lever on the steering wheel into neutral position, from any speed. This brake will hold the car at 10 miles an hour going down the steepest and longest hills, without the so common danger of overheating or burning the brake. IN THIS THIRD BRAKE THERE IS NO BRAKE LINING USED, in fact there are no parts in actual contact. The braking effect is produced by the magnetism of the motor-field PREVENTING the armature from revolving over a certain number of revolutions per minute. The faster you run, the more effective this brake will be.

We have an illustrated catalogue in preparation and will be glad to send you a copy on request.

See our exhibit, Grand Central Palace, C-3, Third Floor



No clutch. No gears to shift.
Electric transmission acts also as self-starter, generator, and electric brake.

New York City, N.Y. Nov. 18, 1914

Mr. R. M. Owen
R. M. Owen & Co.
New York, N. Y.

Dear Sir:-Replying to your inquiry regarding my opinion of the Owen Magnetic Car which I bought from you, will say that I have now run this car about 2000 miles, and in every way it has been more than satisfactory, and has surpassed all claims that you have made for it, and my greatest expectations.

The ease with which I can operate this car in the crowded street traffic of New York City is marvelous. The fact of there being no gears whatsoever, allowing you to keep both hands at all times on the steering wheel, and that it is not necessary to be constantly changing one's gears by shifting the lever as every other make of car requires, is surely a tremendous advantage.

I have not had the slightest trouble of any sort, and as you know, I received practically no instructions as to how it should be operated.

Aside from this wonderful Electrical Transmission feature, the powerful self starting, and powerful electric lighting features, would in themselves recommend it to me over any other car, for while I have had nearly every other starting device and lighting device in the cars I have formerly operated, none of them has ever compared with this.

The entire driving and operating of this car is so unlike any other that it is hard to make a comparison. I have one objection, and only one to this car. It has absolutely spoiled me for driving any other. It now seems such an absolute waste of energy and trouble for me to operate a car, where the shifting of gears, etc., is necessary, that I am using the Electrical Transmission Car which you sold me exclusively.

You have my sincere congratulations on turning out an automobile, the principle of which I firmly believe will revolutionize the entire industry.

Yours truly,
H. Bellas Hess

Automobile Stampings, Drawn and Spun Metal Work of All Kinds

We can handle your sheet metal work, your stampings, your drawn and spun metal work at a much lower cost than you can handle them in your own sheet metal department. We have special equipment for quantity production.

We have 15 acres of floor space devoted to sheet metal work —we have had 33 years' experience in drawing, stamping and spinning of sheet aluminum, monel metal, brass, copper, tin plate and sheet steel—our machines and equipment are the very best obtainable—our men are *experts*.

We have no idle hours in our sheet metal department, no non-productive machines whose overhead is eating up our profits. By keeping our system at top speed all the time we are able to turn out work at lower cost.

15 Acre Plant and 33 Years' Experience at Your Service

We are specially equipped to handle automobile-part work. Our facilities enable us to meet the most difficult situations in light and heavy sheet metal stampings or drawings.

Send blue print or samples and let us estimate on Hoods, Clutch Cases, Covers, Joint Cases, Housings, Pans, Shells, Drums, Gasoline Tanks, Mufflers, Metal Instrument Boards, etc.

You are undoubtedly casting some part that could be turned out better and at a lower cost by stamping.

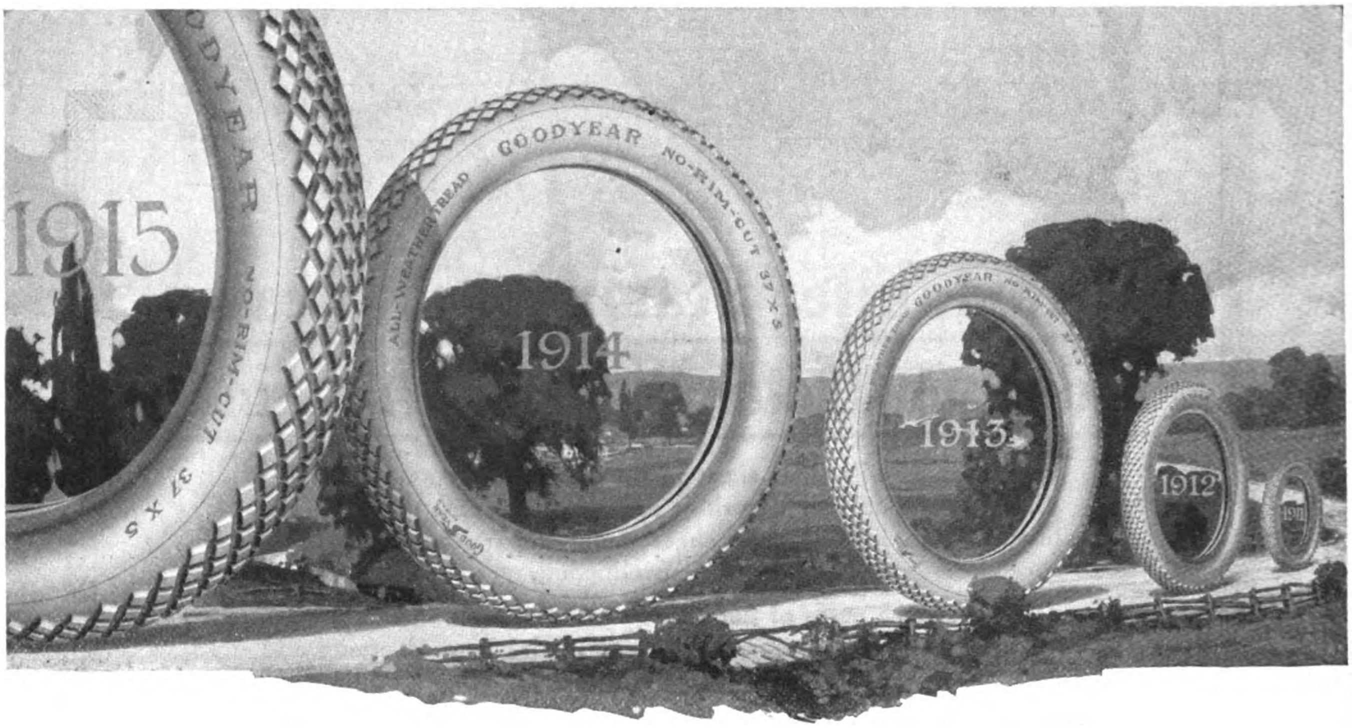
"Knowing How Since '81"



Note How Goodyear Grows As the Years Roll By

1,479,883 Tires Last Year

In the fiscal year just ended we sold 1,479,883 Goodyear pneumatic automobile tires. That's about one tire for every car in use.

It was 26.6 per cent more tires than we sold the year before. It was half as many tires as we had sold in our previous 14 years combined.

It was more per month than we sold per year back in 1909.

It is more than were sold of any other tire that's built.

To Men Like You

We sold these tires to men like you—men who seek quality tires. To men who want safety, strength and endurance. To men who watch tires and compare them.

Some had accidents with tires. Some misused and wrecked them. And some, no doubt, got faulty Goodyear tires.

But there's the record after 15 years—after millions of tests and comparisons. The final verdict, as shown by sales, is that Goodyear tires are best.

Fortified Tires Five Exclusive Ways

Goodyear Fortified tires protect you in five exclusive ways.

One combats rim-cutting in the most efficient way that's known.

One means safety. These tires are held on by an unstretchable tire base, in which we vulcanize six flat bands of 126 braided wires.

One saves needless blow-outs. Our "On-Air" cure—which costs $1,500 daily—prevents the countless blowouts due to wrinkled fabric.

One—a patent method—reduces by 60 per cent the risk of tread separation.

And one combats punctures and skidding. That's our All-Weather tread—tough and double-thick, flat and smooth-running, sharp-edged and resistless.

All these features are in Goodyear Fortified tires. Not one of them is found in any other.

Let Them Prove

This isn't written to sell tires, for tires must sell themselves. We simply urge you to test the tires which won this matchless showing.

They outsell any other. They are gaining new users fast. They are fortified in exclusive ways against five major tire troubles.

You cannot, we argue, be fair to yourself without proving out these tires. And now, with the new year, is a good time to do it.

Any dealer will supply you if you say you want Goodyear tires.

HERZ PLUG

"Bougie Mercedes"

$1.50 postpaid, or from your dealer.

is the result of 20 years of study, experiment and improvement. Its marked superiority over ordinary Plugs is due to the distinctive features of its construction. The insulation is Unbreakable Double Stone (Blue Enameled); there are Four Sparking Points; the electrode of Platinum-Alloy will not burn away; and the Plug is self-cleaning. Every HERZ PLUG is guaranteed a year.

There are special HERZ PLUGS for the Amplex, White, Ford, Pierce-Arrow, Pullman and Overland. Write for the Plug that is best suited to the needs of your particular motor. For most motors, the standard HERZ PLUG is best adapted.

HERZ MAGNETO ensures a fat, hot spark even at a low speed. Compact, reliable, dust-proof, waterproof.

HERZ DISTRIBUTOR provides, with good single coil, an accurately timed and permanently reliable ignition outfit. Very small yet perfect in every detail.

HERZ PATENT DETACHABLE TERMINALS are ideal for convenience. Easy to attach, and they stay attached, making a perfect connection. Equally easy to detach.

HERZ MINIMAX GARAGE PUMP is as inexpensive as a thoroughly efficient Pump can be built. No leakage losses. Can be attached to any lamp socket. Height 30 in., length 35 in. Made for any kind of current. Pressure up to 200 lbs. Splash lubrication.

HERZ TIMER gives the most exact timing independent of the speed. It saves current

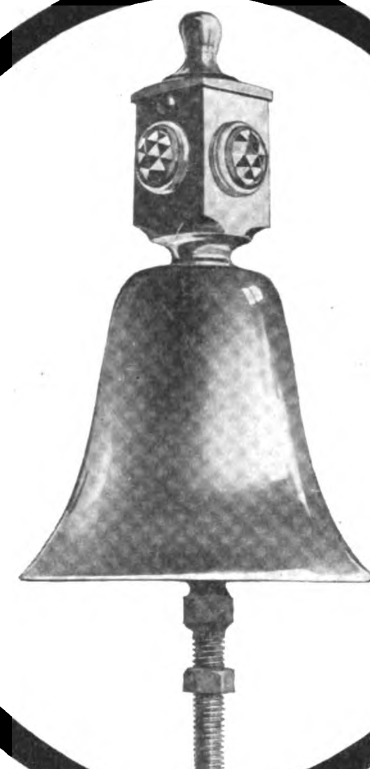
HERZ TAPE GRIP provides the perfect connection between metal pipe and rubber hose. Quick and easy to apply.

HERZ & CO., 245 W. 55th St., (near B'way) New York

THE TRINITY BELL

Warns Both Eye and Ear

The Signal That Never Offends



Made in three styles: Model A—3½ inches in diameter, with Red Light. Especially adapted to the smaller cars. Price, complete, $6.

Model B—5 inches in diameter, with Red Light. Most effective for Roadsters, Runabouts and Touring Cars. Price, complete, $10.

Model C—6 inches in diameter, with Red Light. Preferable for Limousines, Heavy Touring Cars and all trucks. Price, complete, $12.

Any of these bells may be secured with an ornament instead of the Red Light, at no advance in price.

All prices include complete equipment for installation, including 12 feet of best insulated wiring, choice of bracket (for running board, fender, cowl, dash or radiator cap), push button, bolts and washers.

An effective warning signal that sweeps the road clear, without giving offense, is essential to the equipment of every automobile. The clear note of a perfectly made bell—the best of all warning signals—seldom fails to secure the right-of-way, even in crowded streets.

Such a motor vehicle warning signal is the decisive, convincing, effective, TRINITY BELL, a combined alarm and flash, that warns both eye and ear—and never offends.

The bell proper is surmounted by a small Tungsten light, with three red lenses that flash a warning the moment the signal is sounded. Kewpies, Billikens, Policemen, Red Cross or lodge emblems can be supplied in place of signal lamp, at same price.

The TRINITY BELL responds instantly to the touch of hand or foot, on the push button, and is so simple that it can't get out of order. Is impervious to dirt or water. Has water-proof enameled coil, and is cast from the finest bell metal, heavily nickeled. Beautiful in tone. Contact points of pure platinum. Solid as a rock—will not rattle.

Answers all requirements of law, and is absolutely guaranteed. Protected by patents. *Infringers will be prosecuted.*

Dealers and Jobbers:—This easy seller is having a big run. Write for our proposition today, and get your agency early.

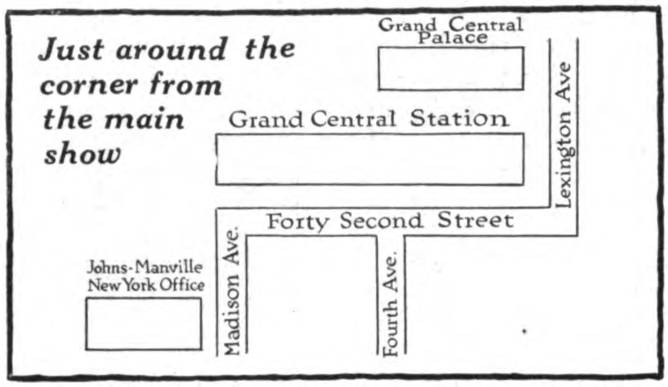
Johns-Manville Accessory Show

January 2nd to 9th Inclusive, Madison Ave. & 41st St. New York



Every Accessory Exhibited Here Holds a Personal Interest For Every Manufacturer, Dealer and Car Owner

DURING the week of New York's Automobile Show we shall devote the ground floor of our New York Building to an exhibition of J-M Automobile Accessories.

In whatever capacity you are interested in accessories your attendance at this exhibition will surely result to your profit.

Please note the convenience of our location to the Grand Central Palace, as shown by the map above.

J-M Accessories on Exhibition

Jones Speedometer

The standard speedometer of the standard type, Centrifugal. Absolutely and permanently accurate, unaffected by temperature, altitude or vibration. More Centrifugal Speedometers will be used on cars manufactured in 1915 than all other types.

Long Horn

The horn that insists. Powerful warning qualities, great reliability, and construction that lasts as long as the car. The horn you want if you're looking for signal safety and the horn you will buy if you compare values.

J-M (Mezger) Soot-Proof Spark Plug

Carefully designed and constructed, embodying the best skill and labor and giving the best service and satisfaction of any high-grade automobile plug. A guaranteed product of the most efficient manufacturing methods.

Carter Carburetor Multiple-Jet

A different principle but one of proven greater efficiency. Excels as a gasoline saver. Increases power and flexibility to a remarkable degree. Results unconditionally guaranteed.

JOHNS-MANVILLE SERVICE COVERS THE CONTINENT

H.W. JOHNS-MANVILLE CO.

Madison Ave. & 41st Street New York

½ Ton Less Weight

The New Light Baker Electric Coupe weighs 2913 lbs.—*a full thousand pounds less* than any of the big heavy five-passenger electrics, and *from 400 to 500 pounds less* than ANY enclosed electric of high grade make. Mere reduction in weight is no advantage in an electric if secured at a loss of speed, mileage, power, strength or comfort. The achievement of the Baker is in its light weight

PLUS FULL SPEED
FULL MILEAGE
FULL POWER
FULL STRENGTH

The speed is 23 miles per hour—the highest ever built into an electric coupe. As for mileage, no electric made gives more per battery charge. In point of power, this light electric will negotiate any hill that *any* motor car can climb. And it will *stand up* through years of hard service, for it has the same structural strength which has characterized the Baker chassis and body for over fifteen years. (Baker Electrics have always been light weight cars.) And in addition, with so much less weight to carry,

The New Light Baker Electric Coupe

is *much easier to handle* on rough pavements or in congested traffic—it steers and turns with the least effort. There is *less wear and tear* on the car; tires last longer; *upkeep expense is reduced.* In short, this electric becomes more than ever a source of pleasure, because of its lighter weight.

In style and beauty the New Light Baker has set a new standard. Needless adornment has been supplanted by a rich, simple refinement. The color effects are attractive and novel. There is not a more luxurious automobile made.

In the face of these facts, is there any good reason why you or your wife should lug around from a quarter to a half-ton of extra dead weight in an electric?

The Baker Double Drive Brougham

is one of the most luxurious electrics of the larger type that has ever been built. It closely resembles the New Light Coupe in general design, the difference being in its larger proportions to accommodate five people instead of four, its double drive feature which enables operating from either front or rear seat, and its seating arrangement. For those who require a large five-passenger car this imposing brougham, equipped with every known motor car refinement, is an ideal model, *and for a car of its size it is lighter than any other electric made.*

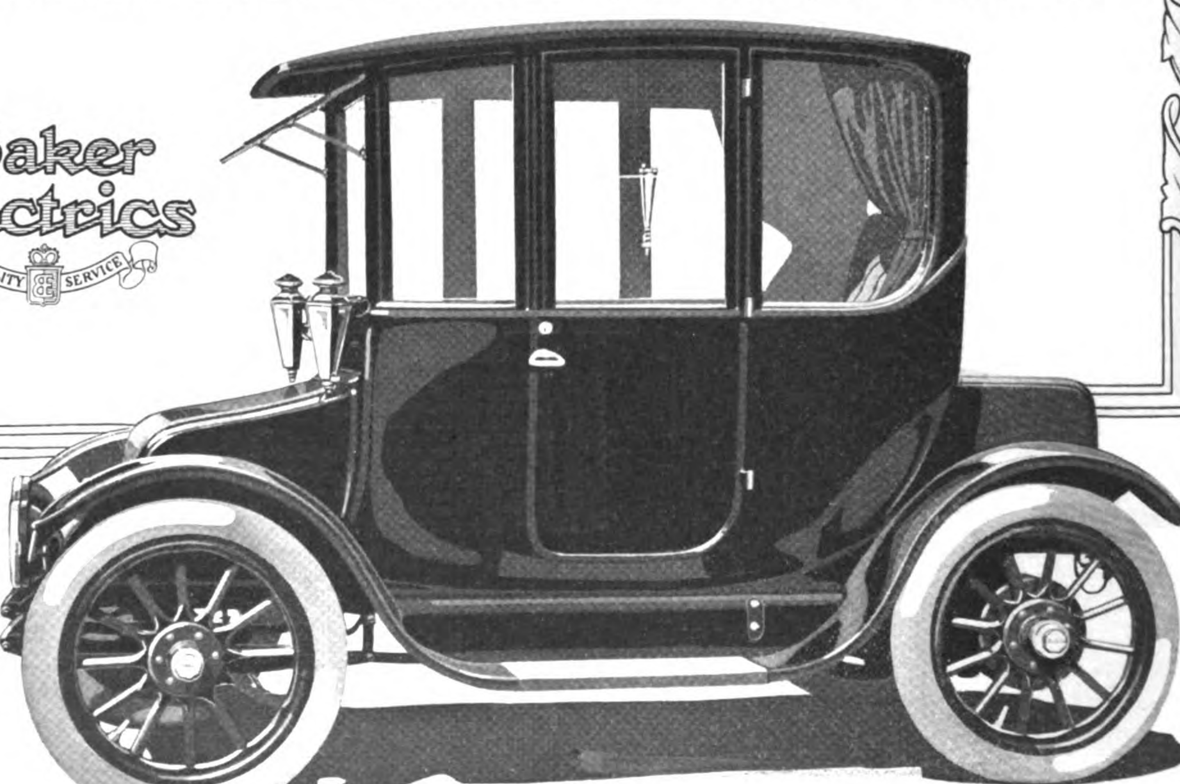
Before you buy an electric, read page seven of the new Baker catalog, mailed on request.

PRICES—BROUGHAMS: Worm gear, double drive or front wheel drive, $3250; COUPES: New Light Baker, worm gear, lever or wheel steer, $2800; BEVEL GEAR COUPE: $2600; ROADSTERS: Bevel gear, lever or wheel steer, $2300.

Also a complete line of commercial trucks from one to five tons.

THE BAKER MOTOR VEHICLE COMPANY, CLEVELAND

Baker Electrics
QUALITY SERVICE



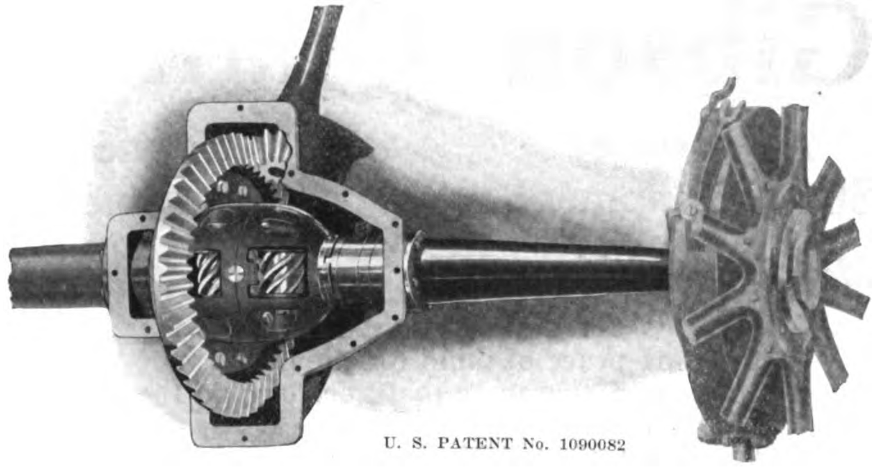
The New Light Baker Electric Coupe.

Price $2800.

America's Greatest Gear Factory Makes the "M & S" DIFFERENTIAL

STOPS THE SKID BEFORE IT STARTS.

INTRODUCES SAFETY TO THE AUTOMOBILE.



U. S. PATENT No. 1090082

Europe wanted trucks with a differential lock. The M & S does all that a lock will do, & a great deal more as well.

The Brown-Lipe-Chapin Co. of Syracuse, the largest makers of Differential Gears, have contracted for the American manufacturing rights of the M & S and can now supply sample gears to car manufacturers' own specifications.

Jeffery Adopts "M & S"

The "Jeffery Quad" used by the U. S. Army and selected for use in Europe is equipped with M & S Differentials. Eight big manufacturers are now making exhaustive tests with a view to equipping their cars with this new improved Differential which gives an entirely new conception of rear axle efficiency. Some car makers are already satisfied and have closed contracts for next year.

"M & S" Gives Equal Pull on Both Rear Wheels

This means that you can **make shorter turns**—that you **save wear on tires** and add from 500 to 1,500 miles to their life. That you **get more mileage** per gallon of gasoline—that **all the power** of your motor is used for driving the car instead of some of it being lost, as it is by the old style differential.

Your Rear Wheels Can't Spin

You can get out of mud holes, sand or snow if the wheel has even the slightest traction. Your engine can **pull greater loads** with less strain—your car **runs smoother** and more evenly and the **danger of skidding** on slippery streets or in mud is largely done away with.

See the "M & S" Differential at Shows—At the Exhibit of the Brown-Lipe-Chapin Co.

Learn the secret of the new mechanical principle demonstrated by the "M & S" which has caused engineers and manufacturers to marvel at the results given by this wonderful new differential. Absolute proof will be given that the "M & S" Differential will do even more than we claim.

A Special Type "M & S" for Ford Cars

In order to give Ford owners an opportunity to increase the efficiency of their cars and to provide for Ford differential replacements a special type M & S has been designed for the Ford Car.

Any mechanic can install it in a few hours. The cost is only a trifle more than the regular Ford bevel gear differential. But the advantages are so evident that no Ford owner will be satisfied with his present differential when once he has driven a Ford equipped with the M & S.

Dealers in Ford parts and accessories can get particulars regarding territory, prices and approximate delivery dates by writing the M & S Gear Co., 1528 Grand Avenue, Kansas City. Order for your Ford now.

If you don't go to New York write for further particulars and literature

For particulars regarding the M & S as standard equipment for pleasure cars and trucks
BROWN-LIPE-CHAPIN COMPANY

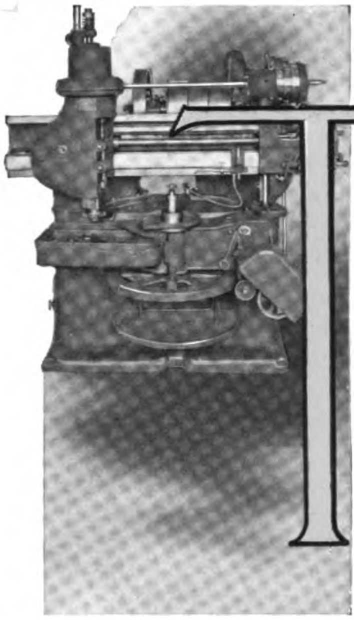
BROWN-LIPE GEAR C^o

SYRACUSE
N·Y· U·S·A·

BROWN-LIPE-CHAPIN C^o



THE Brown-Lipe Gear Company originally came into existence in the early days of the bicycle industry as manufacturers of sprockets and two speed gears for bicycles. From that humble start has grown two gigantic manufacturing institutions that supply today a big percentage of the automobile manufacturers of this country with their differentials, transmissions and control sets. In the plant of the Brown-Lipe-Chapin Company are produced the differentials, while the Brown-Lipe Gear Company confines its manufacturing facilities to the production of the various types and forms of transmissions and control sets. Although the holding interests of the two concerns are practically identical, each occupies its own manufacturing establishment, and each is operated just as separately and distinctly as though they were separately owned and geographically located a thousand miles apart.

As the demands of the automobile industry increased by leaps and bounds, and as the standing of the Brown-Lipe products grew more and more pronounced, it became an absolute necessity for greatly increased manufacturing facilities to supply the industry with Brown-Lipe products. So the single factory which had been enlarged time and again became so inadequate that the two specialized businesses must be separated.

New Company Formed

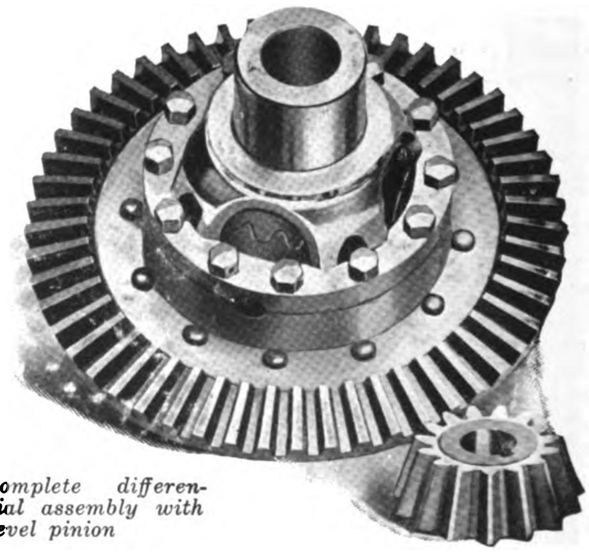
To accommodate this change a second company —the Brown-Lipe-Chapin Company — was organized and a mammoth new plant erected for the sole purpose of handling the differential end of the business. That these are incontrovertible facts may be well realized by the simple statement that in twelve recent consecutive months the output of Brown-Lipe products aggregated something around five millions of dollars, with a labor payroll in excess of a million—all for the production of these three component parts of a car.

The publication of this advertisement and the advertisements that are to follow, is based purely upon a desire to justify in the minds of dealers and consumers the wisdom of car and truck manufacturers in depending upon the Brown-Lipe organizations for such a vast percentage of these working parts.

When it is considered that the question of price has little or nothing to do with the sale of Brown-Lipe products, the simple fact of their dominating to such a marked degree, must evidence beyond contradiction the superiority of these Brown-Lipe products.

But we are not content to assume an air of independence and let our showing tell its own story, for we feel that around this enormous production can be built a story of modern manufacturing and merchandising that will give every user of Brown-Lipe products added confidence in his use of them, and which will give added emphasis to the sagacity and keen business judgment of the manufacturers who place their absolute dependence upon these products.

To the average car owner, as well, even, as to the ultra-intelligent car owner, and in many cases to the absolute trade itself, there is perhaps less known of the real problems and intricacies of gear manufacture than about most any other part of the car today. In the commonly accepted sense of the term, a differential is an unknown something that allows motor-driven apparatus to make a turn without breaking something, and the transmission is an unknown something that admits of various speeds of this motor-driven apparatus by the simple shifting of the lever. It is our purpose in this advertising campaign to set forth first in this announcement a general story of what these products are, and how they are made, and then in subsequent advertisements to show in detail the many and varied problems



Complete differential assembly with bevel pinion and methods necessary for the manufacture of these products.

It should be remembered first—that in the generally accepted sense of the term, all Brown-Lipe products are of special construction; true enough, differentials are standardized—true enough, transmissions are standardized. But each and every car presents its own peculiar characteristics which, in most cases, require special engineering thought in designing such products as lend themselves most admirably to the particular characteristics of the car in question.

To take care of this phase of the situation, separate and distinct corps of engineers are employed, whose constant labor is not only to keep pace with advancements in design, but constantly to co-operate with the manufacturers of the country in the special designing of these parts to meet the special requirements of the individual car itself. However, the question of manufacture is largely the same in the various designs, and in describing these products in the following pages we will take as our subject representative products that illustrate the general output of the factories.

DIFFERENTIALS

In ordinary language, a differential is an assembly of gears that enables the rear wheels to move at different speeds. Everybody knows that when an automobile turns a corner the inside wheel—that is, the wheel nearest the curb—revolves slower than the outside wheel.

A simile to this condition is that of a line of soldiers marching. They are all going forward at the same speed; a command is given for a turn to the right; the man on the extreme right of the line immediately begins to mark time—that is, he moves his feet in the same time as all the rest of his fellow marchers, but his steps are very, very short; in other words, he pivots—simply changes his position before the command, to a position at a right angle.

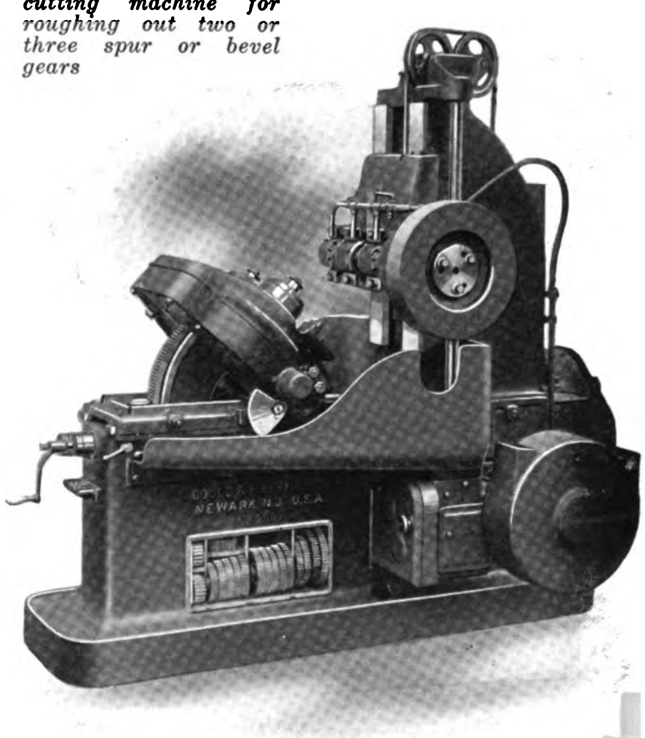
But the man on the extreme left lengthens his stride and increases his speed greatly in order to keep the line straight, each man from the left to the right going just a bit slower than his immediate companion on the left. This really is the action of the rear wheels when the car moves away from a straight line. If, as in the case of a buggy, or of the front wheels, each rear wheel were separate and detached from the other or from any common union, there would be no need of a compensating device.

But in the automobile an entirely different mechanical problem is encountered. The two rear wheels, which are the driving members, are locked to each other by the main axle shaft, when the car is proceeding in a straight line, and are both revolving at the same speed and in proportion to the speed of the engine. Provision, therefore, must be made for a breaking of this lock when the speed of the two wheels becomes different. And it is this function of permitting one wheel to go slow and the other to go fast that is performed by what is known as the differential gear.

The differential set as shown on the opposite page, consists of a pair of cases, a four armed spider, two side gears, four side pinion gears, twelve cap screws, one bevel drive gear, twelve rivets and one bevel drive pinion.

When your car is proceeding in a straight line your power is transmitted through the main driving shaft to the bevel pinion which is meshed with the bevel gear. As the shaft revolves this bevel pinion in turn revolves the bevel gear, which in turn revolves the main axle shaft and the entire differential assembly at right angles to the revolution of the main driving shaft of the engine. The main axle shaft is in two parts, each one attached firmly to its road wheel and differential side gear. This, of course, as you can see, simply makes the wheels revolve and propels the car forward.

Eberhardt vertical cutting type automatic multiple spindle gear cutting machine for roughing out two or three spur or bevel gears



Gleason gear planer. One of a battery of machines used in generating bevel gear teeth

Now then, when a turn is made, instead of the power revolving the entire differential as a unit, the two side gears and the four side pinions immediately begin to turn upon their bearings in the four arm spider. In this way the difference in speed between the two wheels is assimilated or compensated for within the differential itself, by the pinions and side gears.

Were it not for the use of this differential set, every time a car was turned from a straight path there would either be a slipping and tearing of the tires and wheels, or an absolute demoralization of the axle unit itself. The technical engineering data accounting for this really simple performance is extremely mathematical and complicated, and no attempt will be made here to go into a detailed explanation of just why and how these gears admit of these performances. But if anybody is interested enough to wish for the detailed engineering data connected with this operation, we will be glad to have our engineers furnish him with such detail.

As a typical illustration of the care and attention given to the production of a differential we will illustrate operation by operation, just what it means to produce a bevel gear. The same manufacturing conditions are encountered in making all of the gears, and the same care is taken in the handling of each and every part of the set; so that what is applicable to the bevel gear as shown by the following description, is applicable straight through the manufacturing operations of a differential set.

The gear blanks—which are drop forged rings of steel of approximately the shape of the finished bevel gear—are shipped from the forge plant to the differential factory.

The first operation is what is termed the rough forging inspection. These gear blanks are gone over carefully to see that there are no cracks or flaws apparent from an outside examination.

Then a certain fixed percentage of these blanks is drilled sufficiently to get samples of the steel, which samples are sent to the chemical laboratory for analysis. The entire shipment of rough forgings is held in the receiving stock-room until the samples have been thoroughly analyzed in the chemical laboratory to make sure that the chemical specifications of the steel in these forgings is in absolute accordance with the instructions contained in the ordering of the forgings themselves.

In other words, the Brown-Lipe Company knows, from years of study and experience, just what the chemical constituency of each piece of metal should be to give the best results in the performance of its work, and to avoid any possible errors in the manufacture of this steel this chemical analysis is most carefully made. After the chemical analysis the gear blanks are still further prepared for the first machine operation by going through a preliminary heat treating and annealing process. This makes the forgings uniform in constituency throughout and removes the forging strains or internal strains. If the forgings come up to specifications they are then started on the machining operations.

Machine Operations

The first operation in the machine department consists of boring out the center of the gear and facing the back so that it presents an absolute right angle surface to the bored center. This operation is then inspected with micrometers to insure absolute accuracy of size and also is tested on specially constructed jigs.

From this inspection the gear is sent to another machine which turns the face angle and the back angle surfaces. This operation is inspected with micrometers and special gauges to insure proper measurements. At this time the blank is also placed in what is called a running fixture and inspected while running, to insure the trueness of the running gear.

The blank is then placed in a jig, drilled and counterbored. This operation is inspected in a special jig equipped with pins that insures accuracy of boring and counterboring of all the holes. At this point the various surfaces of the blank have been machined to such points of accuracy that the blank itself can be held properly in a cutting machine which performs the next operation known as rough blocking or gashing the teeth.

Another inspection is made, and then the blank is sent to the gear generating department. It is at this point that perhaps the most unique operation in the entire manufacture of a gear takes place.

So remarkable is this process of generating a bevel gear that no attempt will be made to go into details at this time, but rather this matter will be left for treatment in an individual advertisement which will deal exclusively with this problem.

But some idea of the magnitude of the Brown-Lipe-Chapin Company may be gained from the statement at this time that the battery of Gleason gear generating machines installed in the Brown-Lipe-Chapin works is the largest battery of machines of this kind in the world.

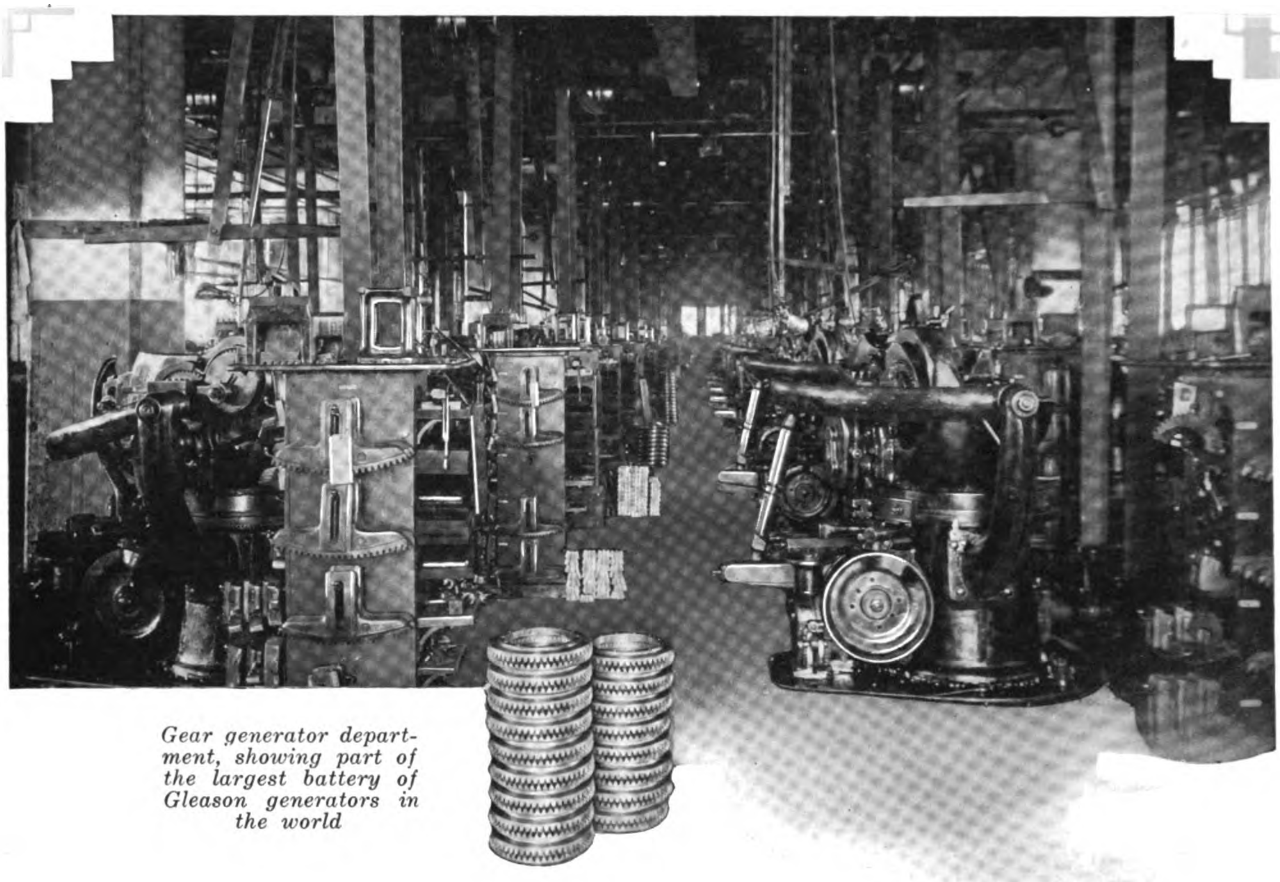
When the gear blank comes from this operation it is completely machined, and to all outward appearances, ready for work. To insure again positive accuracy in every way this gear, with all the machining operations completed, is sent to the inspection department where it is given a running test for sound, for the condition of tooth bearing and also for tooth measurements.

Then comes an operation which really calls for the most expert knowledge, and for the greatest amount of care and watchfulness in the entire manufacture of the product—the operation of hardening and heat treating. Up to this point we have been dealing with a piece of steel of such a carbon content as to admit readily of machining operations. It is obvious that if a piece of metal which is called upon to play as important a working part in the use of the automobile as a bevel gear, were to be assembled into that automobile in so soft a physical condition as to admit of easy cutting, it would be but a short time until that gear would wear appreciably. That would mean looseness of fit, noise and general all around dissatisfaction.

Hardening Problem

So the surface of this gear—that is, the surface of the teeth of the gear, which are the parts subjected to fric-

Grinding department, where side gears and pinions for the differentials are ground



Gear generator department, showing part of the largest battery of Gleason generators in the world

tion—must be so hard as to practically resist wear during the operation of the car. At the same time the body of the tooth as differentiating from the surface of the tooth, must be tough and strong.

As we have shown before, if the surface of the tooth is soft enough to possess features of toughness and strength it is not hard enough to resist wear when in mesh and running.

Inversely, if the whole tooth, that is, both body and surface be hard enough to resist wear on the surface, then the tooth will be brittle and not tough enough to keep from breaking off under the strain of driving.

So that in the hardening department these two contrasting conditions must be faced, namely: to so treat the finished machine blank as to present a hard, wear-resisting surface on the teeth, and at the same time to retain a more soft, but more tough core or body in the tooth.

So these gears are sent to the hardening department and subjected to a carburizing process which hardens the surface of the gear to a depth of 1-32 of an inch, and refines and toughens the core. So wonderful a subject is this question of heat treating that on succeeding pages of this advertisement we will go into the detail concerning the operation of a heat treating furnace.

The hardened gear is then sent to the testing department in the heat treating room, and by a variety of unique tests, is examined as to its hardness and evenness of hardening.

Then the gear is sent to another machine for straightening these gears inasmuch as frequently they bulge out of true during their subjection to the extreme heat. After being straightened the gear is again subjected to running tests and endurance tests, when it is ready for the grinding or sand blasting room. After being polished to mirror smoothness, the finished gear is again inspected for dimensions, and finally is subjected to its last running test for trueness.

You have probably noticed in following through this manufacturing process, that "inspection" and "test" are two words very frequently encountered. It is because Brown-Lipe products are subjected to this careful and exhaustive inspection and testing largely that they enjoy the enviable reputation in which they are held by the manufacturing public. And it is this reason also that accounts in a great measure for the extreme life and satisfactory service rendered by Brown-Lipe products.

HEAT TREATING

As indicated in one of the preceding pages, there is perhaps no single operation or handling which is fraught with so much importance, or which has required so much experimentation in the perfecting of the process, as that of the heat treating of the metal after it has been machined. For this reason the heat treating departments of the Brown-Lipe Companies are beyond doubt the most thorough and most modern, both in physical and mental equipment, of any heat treating plant known, and the methods employed to insure absolute results are most extensive and complete.

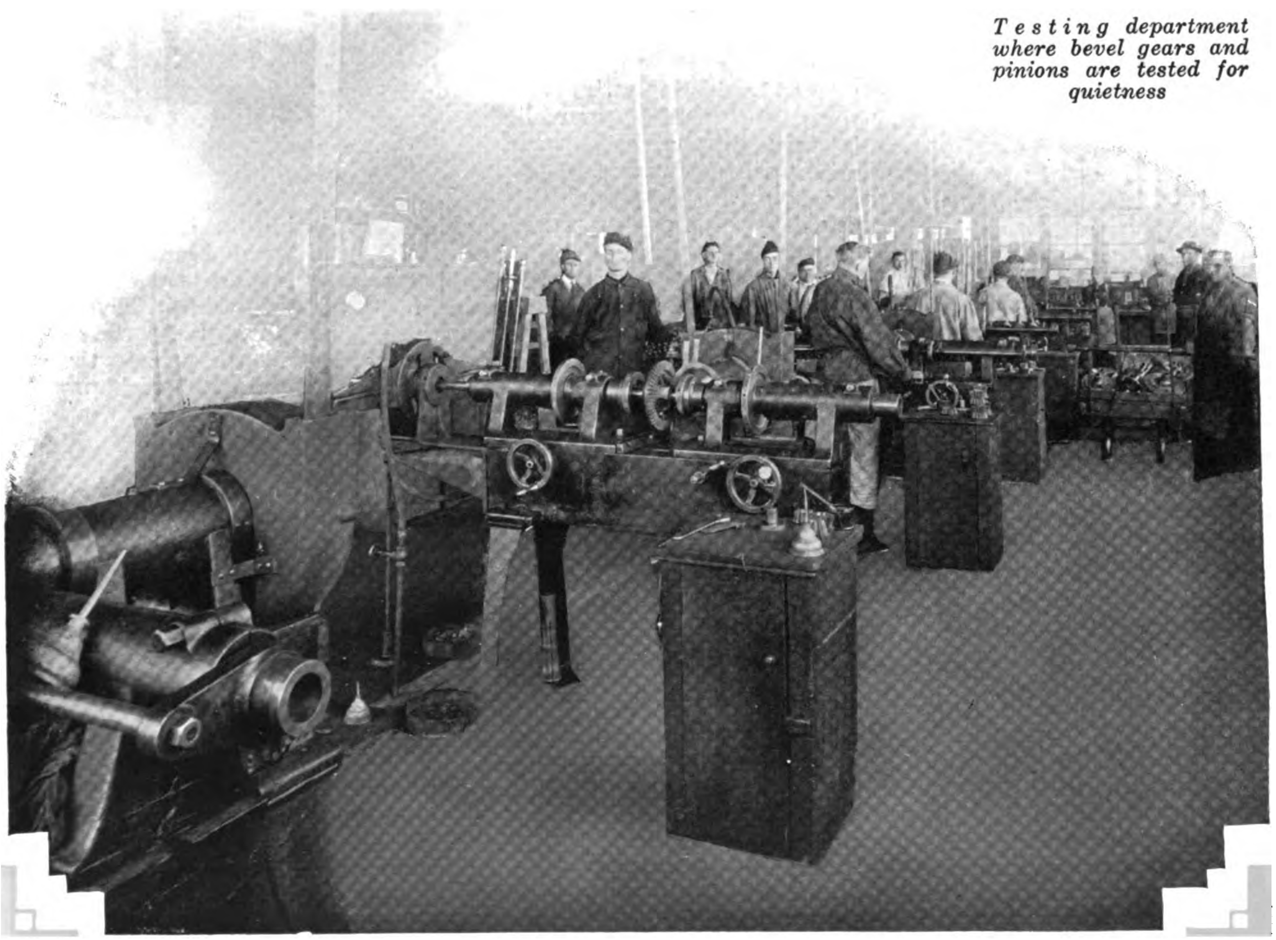
When the gears are brought into the heat treating department they are first turned over to an operator who lays them out to be placed in a certain furnace. Each individual gear is

Gears Numbered

then numbered in such a manner that two or three years afterwards, if the case requires, the gear can be identified as having been heated upon a certain day, in a certain furnace,—in a certain pot and the position in which that pot was placed in that furnace. The exact number of hours it was in that furnace and the amount of heat that was put into it can also be told from individual records that are kept of each furnace during each heat of every day.

After the gears are thus identified, the screw holes and rivet holes are plugged with fire clay so as to prevent the carburizing mixture from coming into contact with anything other than the surface. Together with this secret carburizing mixture the gear blanks are then packed in hollow center round fire pots, the tops of which are luted on with fire clay so as to make the pots practically hermetically sealed. These pots are then put into the furnace which has been brought up to a certain temperature, and the heat treating process has been started.

It must be understood that the results obtained by this heat treating—that is, the laying of 1-32 of an inch hard surface and the retaining of a comparatively soft, tough, strong core—is accom-



Testing department where bevel gears and pinions are tested for quietness

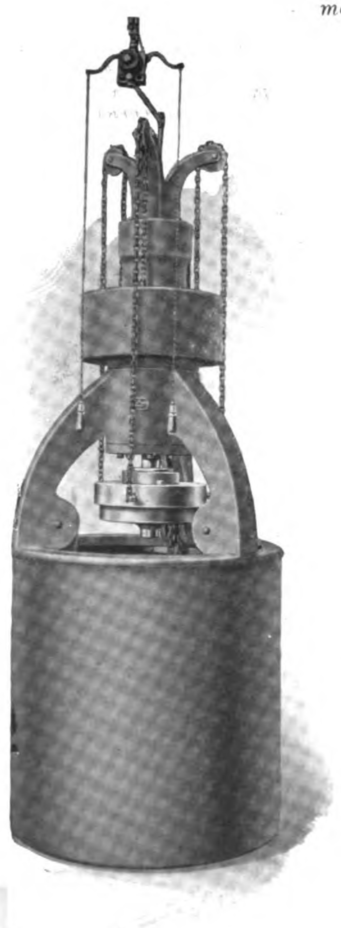
Case hardening and heat treating department—carburizing pots at right

plished by driving carbon into the surface of the gear while it lays in the carburizing mixture in the furnace.

As a matter of fact it is the gases generated inside of this hermetically sealed fire pot that do the work. When the rough blank of a carbon steel gear is brought to the heat treating department it is uniformly of about .20 carbon from center to surface; when it leaves the heat treating department the center remains substantially the same with a very slight variation to both surfaces, while the surfaces themselves to a depth of 1-32 of an inch must contain 1.00 carbon.

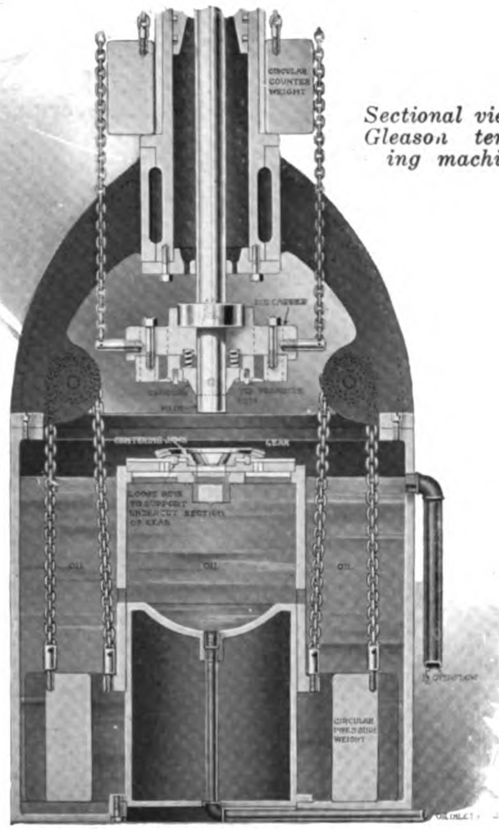
Heat Measured

A somewhat homely analogy to the heat treating of metal is that of baking bread. The molded loaves are placed in the oven and the fire is maintained at a certain heat for a certain length of time. If the oven be too hot the outside of the bread is hard and the inside is raw. If it be too cool and if it required too long a time to bake the bread, it is heavy and unsatisfactory in every way.



Gleason tempering machine—Straightens gears while hot

And just so with the heat treating of metal, only to an unlimited greater degree. Years of experience and experimentation have shown metallurgists just the best method to follow to produce given results, and where our bread-bakers only look at the oven once or twice during the baking, there is the most accurate and most absolute check kept on every furnace during every minute of its work—and here it is that the real heat treating takes place.



Sectional view of Gleason tempering machine

Connected to each furnace is an electric heat registering device known as a pyrometer. This is really an electric thermometer so constructed that it registers the heat of the furnace either at the furnace or many feet away from the furnace.

In the Brown-Lipe plant each furnace pyrometer is connected with a registering device in a room in one end of the building, before which sits an operator whose sole duty is to read and record the temperature of each and every furnace every five minutes during the carburizing process, which averages about 7 1-4 hours.

Just let that thought sink into your mind deeply —every five minutes of all this time an absolute record is made of the condition of the furnace. This operator knows that when the metal was first placed into the heating furnace that it registered a certain temperature, and it is his duty by these five minute checkings to see that the temperature of that furnace is constantly and steadily raised a certain number of degrees at certain regular intervals until at the end of the time necessary to complete the heat, a certain fixed temperature shall have been attained.

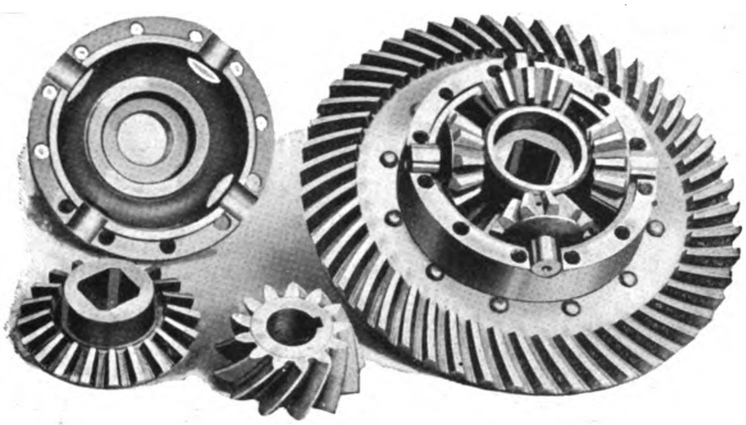
In other words, it is his duty to see that, if the temperature of a certain furnace at starting is 1185 degrees F., after the doors have been closed and the fire commences to work regularly, that furnace shall continue to increase its heat a few degrees at a time, until at the end of 2 1-2 or 3 hours according to his instructions from the metallurgist in charge of the operation, the heat in that furnace shall be 1600 degrees F., without the temperature ever having fallen backward during the process of raising it.

And in the watching of this operation this furnace is not allowed to vary over 10 degrees one way or the other. As the operator looks over his charts, if he sees that one furnace is not rising as fast as it should, or is rising too fast—that is, if the variations are 10 plus or minus from the curve which the heat should follow, he immediately notifies the man in charge of the furnace. If there is still a variation, the foreman is notified, and in turn the metallurgist himself in charge of the plant is informed and consulted.

After the gears have been properly carburized they are drawn from the fire and quenched in an oil bath, the oil of which is held at a certain definite temperature by an efficient cooling system. This treatment is for the purpose of refining the core or the central tough portion. Then when the gears are cooled to the temperature of the bath they again are heated up uniformly to 1425 degrees F., for the purpose of refining the hard shell or case which has been left in a very crystalline condition, due to the high heat used in refining the core.

Occasionally it is found that the gears in the process of case hardening warp out of true. To compensate for this warping such gears as have been found to be warped are straightened while hot in the quench bath by means of a newly devised straightening machine used for that purpose. The heat treatment completed, the gears are then sent to the testing department in the heat treating shop, and most thoroughly and carefully tested almost tooth by tooth to

Fractured gears showing case hardening results. Lower piece faulty—no case hardening. Upper piece good. Note hard strip around edges of fracture at right of good gear



Spiral bevel drive differential partly dissembled and spiral bevel drive pinion

which is known as the fire end. To insure absolute uniformity and exactness of temperature, these fire ends are changed on every pyrometer every Saturday so as to eliminate any possible danger of undue wearing or leakage of current of any sort. These new fire ends, previous to being placed in the furnace are standardized against a Bureau of Standards Couple which is gotten out in Washington, D. C.

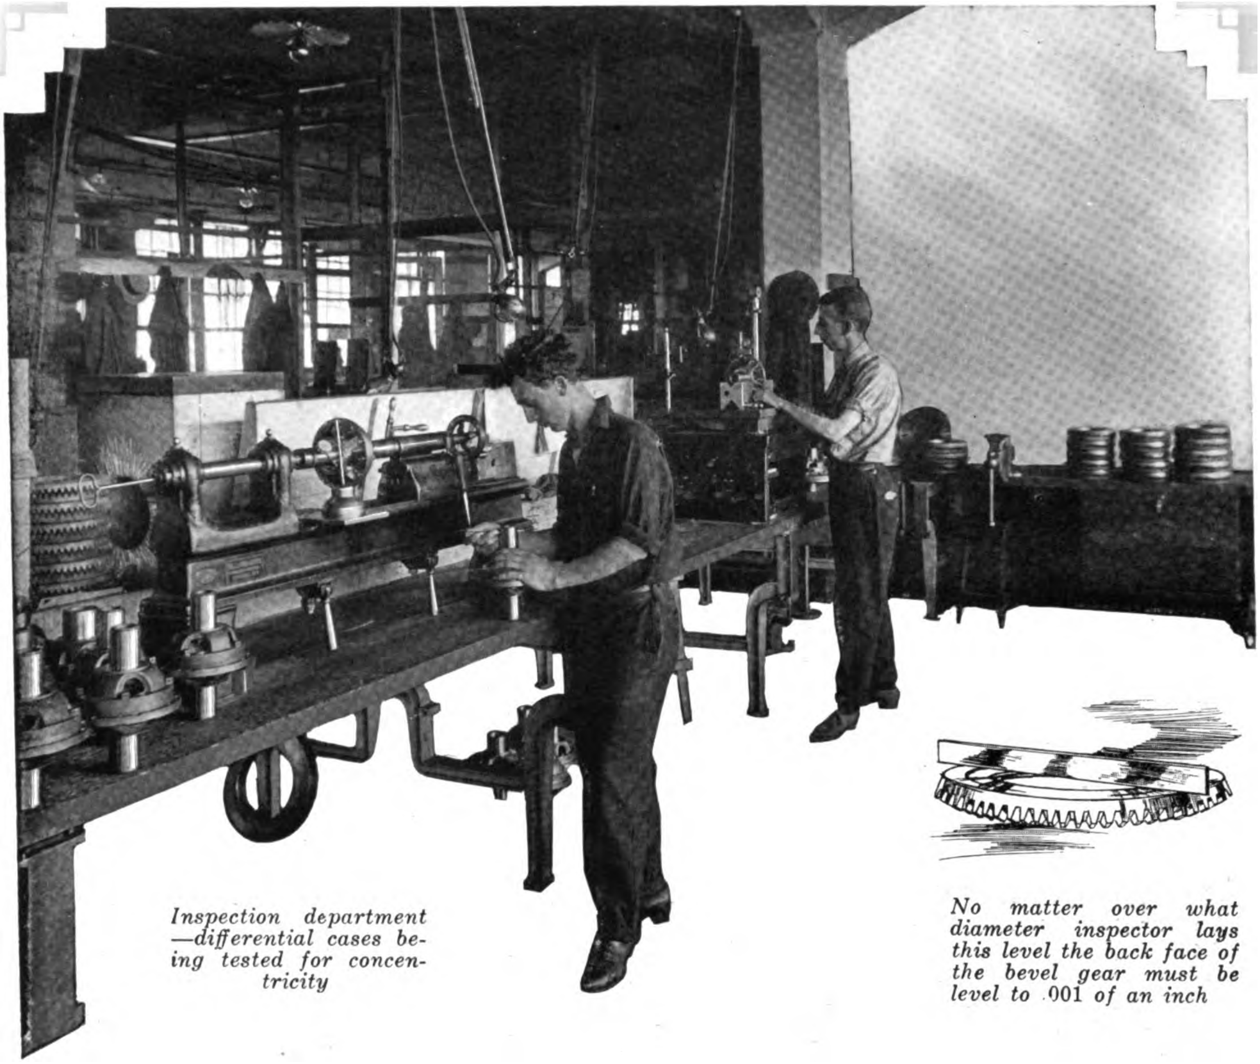
be sure that the proper amount of hardness and the proper depth of hardness have been obtained.

Just another little instance in connection with the accuracy employed throughout this heat treating department. We wish to refer again to the question of the pyrometer. These pyrometers operate on the principle that when you place two different metals in contact—for instance, copper-nickel alloy and iron — and apply heat at the point of contact, an electrical current is set up. In these pyrometers, therefore, there is a contact so constructed, which goes inside of the furnace and

From the recording station to the fire end of the Brown-Lipe heating plant is a distance perhaps of a hundred feet, and wires connected with the pyrometers at the far furnaces must be carried up to the other end of the building to the recording table.

Ordinarily electricity is conducted through copper wires, but in the conducting of the temperature variations from the pyrometers in the Brown-Lipe furnaces to the recording table, a condition arises, so minute in importance to the average lay mind as hardly to be realized, that calls for a change in this general practice of

Differential Stock Room
Bevel gears in fore-ground



Inspection department —differential cases being tested for concentricity

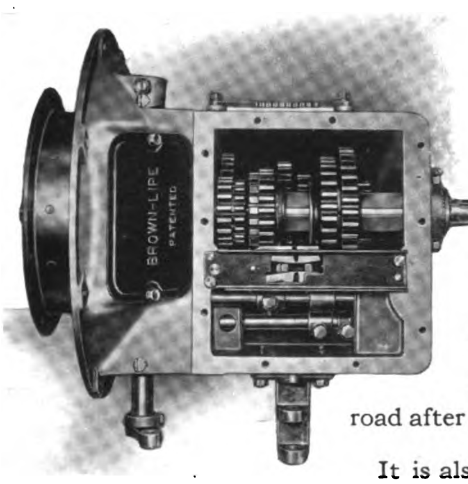
No matter over what diameter inspector lays this level the back face of the bevel gear must be level to .001 of an inch

conducting the current by copper. As we have stated before, whenever and wherever two different metals are united in the presence of heat, an electric current is set up, and in these pyrometers copper and iron are united in the furnaces to set up this electrical current. Now, then, if another union of copper and iron were made to the iron terminal of the pyrometer outside of the furnace—as would be the case if a pair of copper wires were used to transmit this current from the furnace to the recording table—a counter current would be set up at the second point of contact of the copper wire with the iron. So, to avoid even so minute a variation as might be occasioned by this second junction of copper and iron even at a very low temperature, and which would be small, a special insulated iron wire is carried straight through from the pyrometer to the recording table.

Emphasis is laid upon this apparently unimportant detail solely for the purpose of carrying conviction on the point that every single possible safeguard to insure the greatest efficiency in the finished product is employed throughout the Brown-Lipe organization.

TRANSMISSIONS

As is generally known, a transmission set is a combination of gears and shafts that provide for variable speeds and variable power applications to the driving wheel of a car. The necessity for the use of a transmission set is based on the principle that in internal combustion engines the power delivered by the engine is absolutely correlated to the speed at which the engine is revolving; in other words, if at 200 revolutions per minute a certain gas engine is delivering a power impulse of 3 h. p., at ten times that speed, or 2000 revolutions per minute, that engine is providing approximately ten times that power, or 30 h. p.



Transmission

In the driving of every car there are times when great power is required at slow speed, as evidenced in the starting of a car or in driving through mud or hill climbing. It is obvious that it requires more power to move a car from a dead stop into motion, than to propel that car forward on a perfectly level road after it has been set in motion.

It is also obvious that it requires more power at slower speed to drive that car through mud or up a hill than it required to drive it along a level road, and it must be borne in mind all the time that more power can only be obtained through greater speed of the engine.

To accommodate this condition the transmission is built so that while the engine may be turning over at top speed and delivering its maximum of power, you are still able to gear down the car so that it is not moving at top speed. Then, too, a device of some sort is necessary to provide for the question of reverse, or driving the car backward.

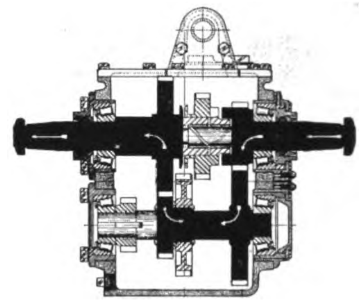
The average transmission set as exemplified in the unit power plant and multiple disc clutch construction consists, first—of the case which contains the gears and shafts. In this case is the driving gear which takes the power from the engine through the driving shaft; then there is what is called the square or rear shaft, on which are mounted two sliding gears, one of which provides the intermediate and direct speed; and the other of which operated in one direction provides low speeds, while operating in the other direction provides the reverse speed, this being a description of a three speed forward and reverse transmission.

Use of Transmission

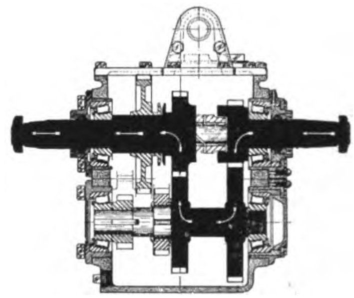
Then there is a counter-shaft which carries the counter-shaft drive gear, the intermediate speed gear, the low speed gear and the reverse speed gear. Of course, there are the bearing retainers and the various bearings which support the different shafts. Then there is what is called an idler, mounted on a stud, which is used in the obtaining of the reverse gear. The use of the transmission is very simple.

The main driving shaft is of course always revolving at engine speed, and when the car is driving on what is called "high" the wheels are turning by means of a direct transmission of actual engine speed from the crank shaft of the engine to the differential gear. When you select your gear, whether it be first or second, you simply throw out your direct connection between the main driving shaft of the car and the crank shaft of the engine through the transmission set, and interpose in the line of drive a set of gears.

An illustration of every day occurrence is seen in the bicycle. The front sprocket which is connected to your pedals,

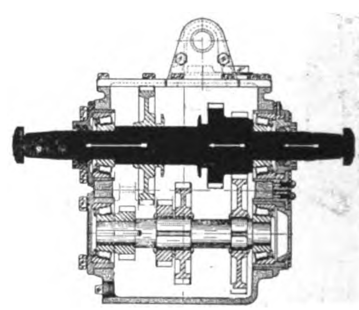


First Speed

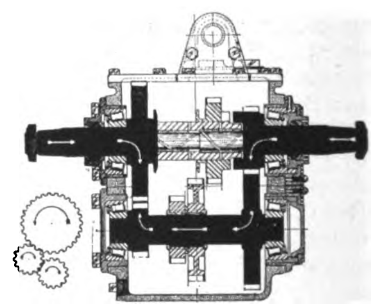


Second Speed

Solid black indicates power line. White blocks in solid black indicate gear meshing—arrows show direction of power.



Third or Direct Speed



Reverse Speed

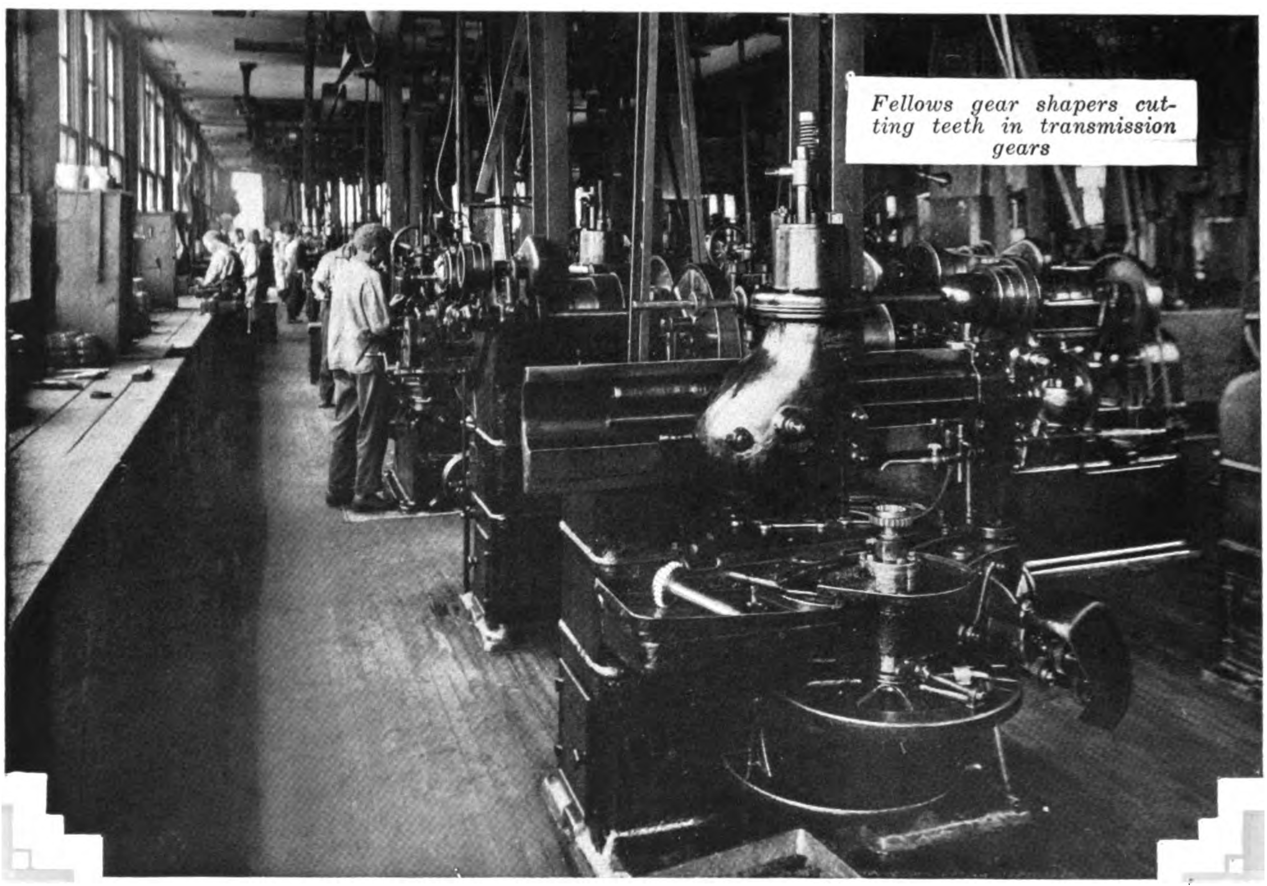
Note that in direct the gears do not play any active part in transmitting power. In the reverse an odd gear called the idler gear is introduced in the train of gears which causes the axle end of the split shaft to rotate in opposite direction to the engine end of the split shaft is a great big gear with a great number of teeth, while the rear sprocket—that is, the sprocket which is attached to the rear wheel —is a small gear with a small number of teeth. For every revolution that one pedal makes, or for every revolution that the big sprocket makes, the little sprocket on the rear wheel, and consequently the wheel itself, makes several revolutions. So that by turning your feet over once you revolve your wheel several times, the exact differential being direct in proportion to the number of teeth on the two sprocket wheels. Now, if you were to put your small sprocket on the pedal of your bicycle, and the big sprocket on the rear wheel—as is usually the case with trick bicycle riders on the stage—your feet would have to revolve two or three times to make the rear wheel revolve once; in other words, the power application might be identically the same at the pedals, but the speed of the bicycle would be different.

In your three speed transmission case the reverse principle of the average bicycle construction is in vogue. For very low speeds you put a gear of small size connected with the engine into operation with a gear of big size connected with the driving shaft of the car. For your intermediate speed you put this same small gear connected with your engine into operation with a smaller gear than used in the low selective, and yet a gear which is larger than the driving gear. And in reverse you simply use three gears instead of two gears.

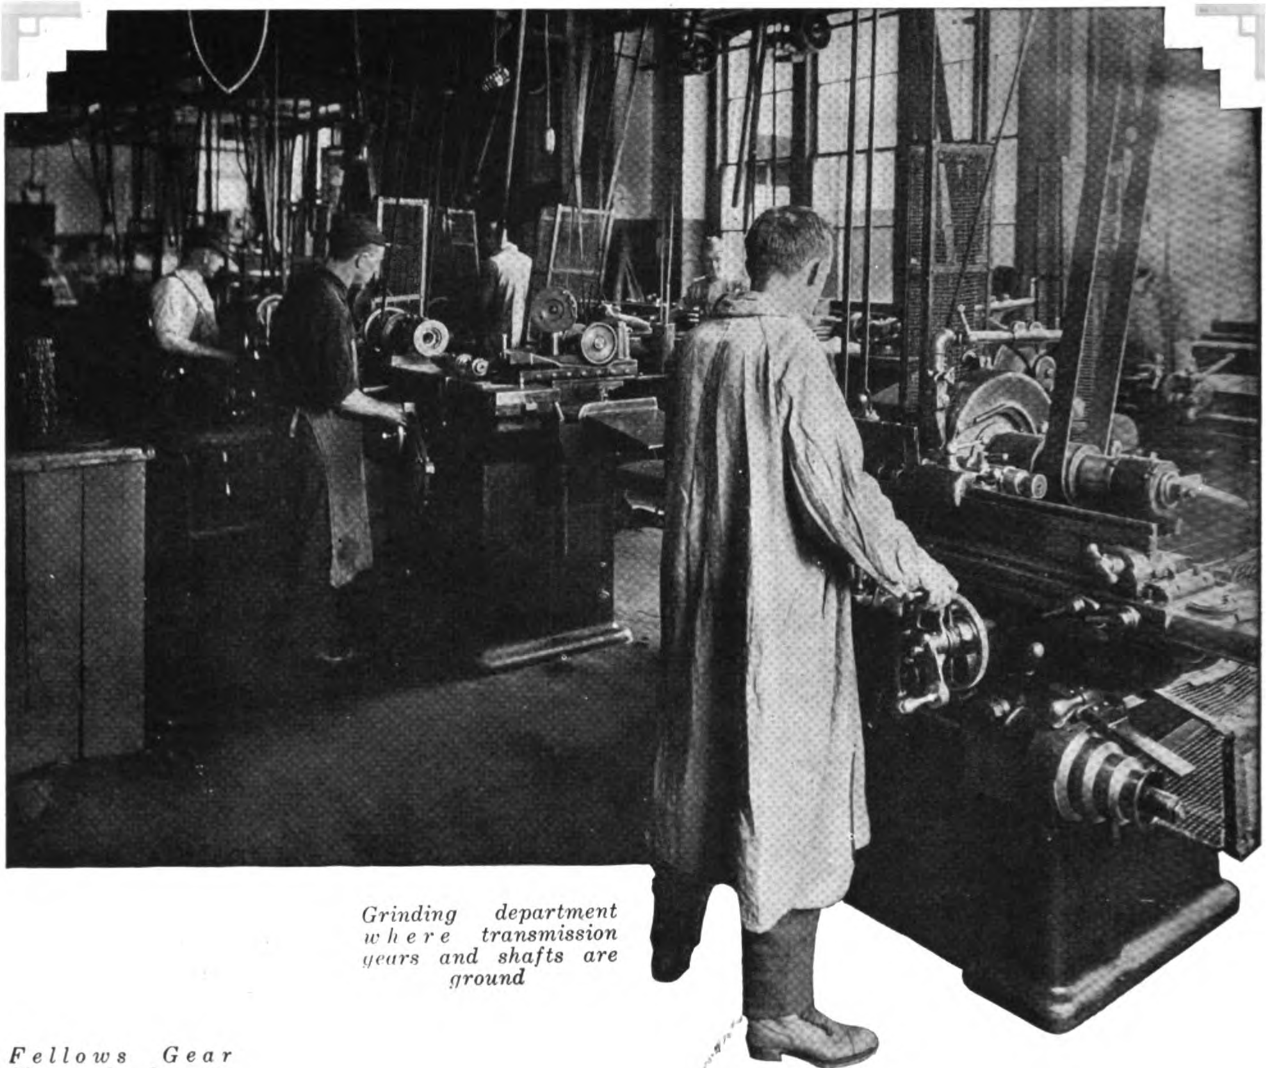
In the case of a four speed transmission where you get your fourth speed on what is called a "step up" you simply call into play the exact bicycle construction—that is, you use a small driving gear with a still smaller gear connected to the main shaft of your car; in other words, for every revolution of your engine the driving shaft of your car is revolving faster than the engine.

In the transmission department the general practice is, so far as the machining and heat treating operation, identical with those described under the heading of "Differentials," with the exception, of course, that in the differential department most of the gear cutting is bevel, while in the transmission department there are no bevel gears.

In the production of the transmission gears in the Brown-Lipe plant, however, there is one feature which is carefully watched, that is perhaps a little at variance with common practice. In the generating of gears several blanks are laid one upon the other, and then put into the gear shaper in such a manner that the cutting tool works up and down over three or four or more gears at the same time.

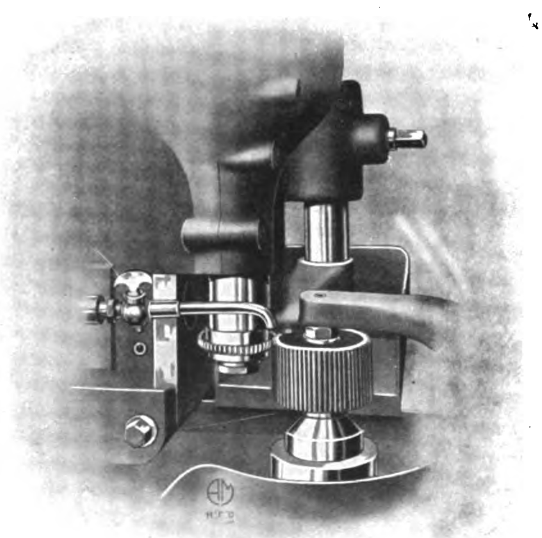


Fellows gear shapers cutting teeth in transmission gears



Grinding department where transmission gears and shafts are ground

Fellows Gear ***Shaper showing cutter at work***

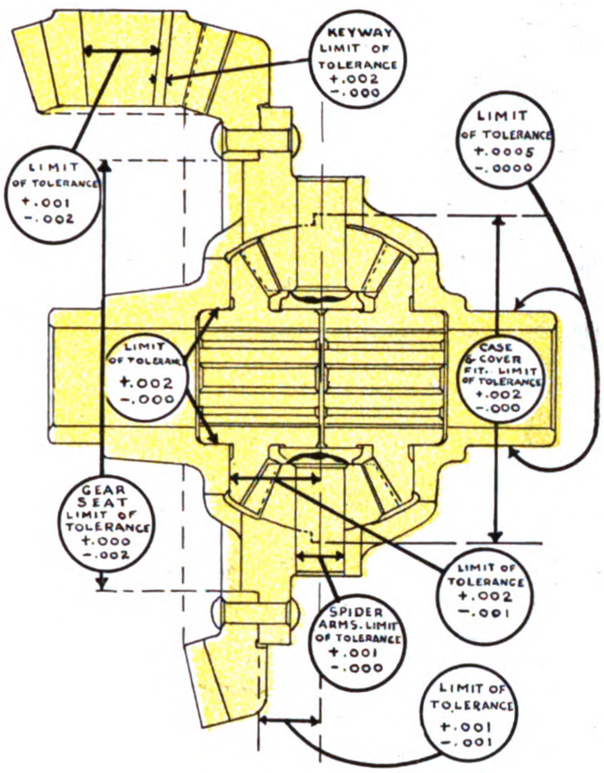


In order to have all these teeth cut at absolute right angles to the face of the gear, or in other words, to have the line of the tooth absolutely parallel with the shaft to which it is attached, the gear blank faces must be absolutely parallel and accurate. So that instead of simply assembling these blanks as they first come from the forge, all the gear faces are first ground absolutely parallel before shaping, then when they are stacked and placed in the gear shaper, the gear teeth must be cut absolutely at right angles with the face of the gear.

It is in this work—this preliminary machine work, that a very marked manufacturing refinement takes place in the Brown-Lipe Plant.

For where in cheap manufacturing this first machining operation is slighted, in the Brown-Lipe Transmission work it is held to absolute limits.

In the construction of the case in Brown-Lipe Heavy Duty Transmissions all the bearings



are mounted in malleable cages which are carefully fitted into the aluminum of the case itself, rather than being mounted directly in the aluminum. This of course is a great deal more expensive method of manufacture but by the same token it is vastly more superior and accurate.

Quality and efficiency, the earmarks of Brown-Lipe products, depend in the final analysis upon the thoroughness of the testing and inspection departments through which those products must pass.

No matter how clever a design may be, it proper materials properly machined are not embodied in the result of that design, quality and efficiency are lacking. It is, therefore, largely due to the thoroughness and completeness of the inspection departments in their checking up, not alone of materials, but of the work performed on the materials, that Brown-Lipe products stand today as unquestionably the standard upon which all competitive products are analyzed.

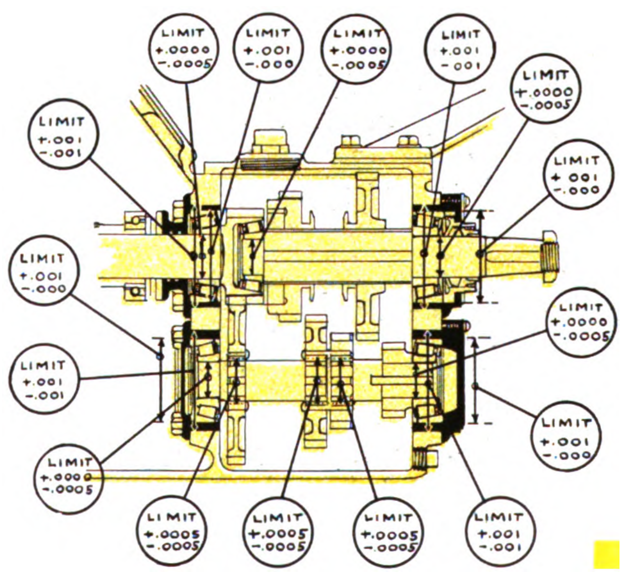
Throughout the machining of every part of every product working limits are enforced in the Brown-Lipe organizations that to the mind of the layman seem impossible of enforcement. The .001 part of an inch is just as much a factor in measurements as an inch itself and the very fact that the Brown-Lipe Companies enforce their workmen to hold themselves down to such microscopic measurements explains in detail just why Brown-Lipe products are better products and just why Brown-Lipe products cost more ultimately as a first cost but why in the hands of the consumer Brown-Lipe products represent the lowest cost.

The illustrations on this page of the differentials and transmissions show the wonderful microscopical limits to which these products are held.

In the differential, for instance, the bevel gear seat must be machined within .002 part of an inch of the indicated measurements on the blue print. The case and cover must fit to a limit of variation of plus .001 of an inch and minus absolutely nothing. The hubs are held to a limit of plus .001 of an inch variation and in the design, wherein we press on the sleeves and grind the hubs, the variation from actual indicated measurement is held as low as .000 1-4 of an inch.

Throughout the grinding of the surfaces of the internal parts—that is, the arms of the spider; the bore of the spider; the back bore and front of the side pinions; the back and hubs of the side gears, as well as the bore of the side gears where spline shafts are used—the limit of tolerance of variation from the blue print is held to .001 of an inch.

And all these and many other measurements are held there, too, for any inspector who allows any one of these measurements to vary from its absolute limitation automatically discharges himself. And what is more, through the working out of our manufacturing plans the inspection of one man is checked by that of another.



In the transmission tolerance limits of .0005 of an inch are encountered more generally than limits of .001 of an inch. Both the main shaft and the countershaft at every bearing fit are held to the specified dimensions within a minus limit of .0005 and with absolutely no oversize. In other words, the instructions to the mechanic who finishes those shafts are that his limit of tolerance

from measurements is plus nothing and minus .0005 of an inch.

Where the aluminum case is bored to furnish a seat for the bearing cage in which the shafts are mounted, the limit is plus or minus .001, while the bore of the bearing cage itself is held to a limit of plus .001 and minus nothing.

The grinding limits for the gear fits on the countershaft are plus or minus .0005 while the grinding limit on the square shaft upon which the sliding gears slide is absolutely nothing. All gears must be concentric — the measurement of concentricity being from centre of the gear to the pitch line of the teeth—to a limit of .001 of an inch.

And so right on through the entire manufacture of every Brown-Lipe product.

Combine these microscopical manufacturing conditions with a design which contemplates only the production of a part that will give the maximum of service with the minimum of weight and practical elimination of noise—

Combine these manufacturing conditions and this superiority of design with the fact that the metal which enters into these parts is most carefully analyzed chemically and held absolutely to the specifications we know to be best suited to the requirements—

Combine these superior points of design, workmanship, inspection and materials with the final fact that this product is treated to a degree of accuracy and perfection almost superhuman to the lay mind and you have again our reasons for claiming that

Brown-Lipe products are unquestionably the standards by which all competitive products are measured.

EISEMANN

waterproof, high tension magneto. Simplicity personified is the keynote of the construction of this new Eisemann product. It is the most accessible, most efficient instrument that has ever been produced, and we are willing to base our contracts on actual tests of this literal statement.

The principal features of simplification are to be found in the new contact breaker which is patented; the method of carrying the high-tension current direct from the collector ring to the distributor without the use of unnecessary brushes and conductors; the method of attaching the cables inside of the magneto and a general elimination of parts by a remarkably clever new design.

And in the increased simplicity and accessibility this new model has also gained much in efficiency. Waterproof, dustproof and practically foolproof, it is the greatest step forward yet recorded by the Eisemann Company in the maintaining of its reputation for efficiency, reliability and durability.

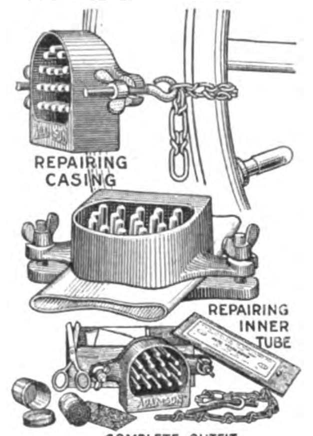
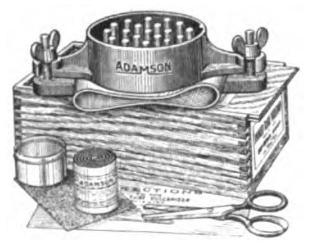
WAR IS HEL-pful!

—to ADAMSON Dealers.

Let's put an ADAMSON Vulcanizer in every "See America first" Kit!



Model "U"
For Repairing INNER TUBES and CASINGS
Price Complete $3.00



Model "T"
For Repairing INNER TUBES Only
Price Complete $2.00

THOUSANDS of people who have been "kiting" away to Europe for their vacations—to "see the sights"—will now stay at home and SEE AMERICA. Many of the better classes of people will be attracted from abroad. We will become the commercial, the educational and the sight-seeing nation.

Let's Capture the Added Domestic Business This Means For Us

Can we not—together—put an ADAMSON Vulcanizer in every "See America First" automobile kit?

There will be more overland travel in the United States —for some time. Motorists will need just the sort of service an ADAMSON Vulcanizer provides.

There is a tendency to economize which, while it may reflect itself in some lines adversely, means YOUR opportunity when it comes to selling Vulcanizers—for Adamson Vulcanizers *save many tire dollars.*

If you sell less of one thing—you can sell more of another! We hope that EVERYTHING is moving out lively! But if you want to create still more activity—get busy with ADAMSON Vulcanizers.

ADAMSON MANUFACTURING COMPANY

Hamilton, Ont., Canada **East Palestine, Ohio**

National Motor Vehicle Co., Indianapolis, Ind.

You will save enough on tires in a year, because of proper inflation, to more than offset the cost of the

MANZEL
ENGINE DRIVEN TIRE PUMP

A pump at $20 that does the work of tire inflation with the absolute minimum of effort on your part, that pumps to the efficient limit dictated by the size of your tires, and then automatically shuts off the air supply, preventing over-inflation, with resulting blowouts, and damage to your tubes and casings.

It is easy to install—"a screwdriver, a file and a wrench"—these are the tools you need, and you don't have to pay a mechanic to put it on for you. Once on it's on to stay. It weighs less and occupies less space than any other pump of the same capacity.

When you want to use it, simply couple on your hose connection, throw your pump gears into mesh, start your engine, and sit back for two or three minutes—your tire is inflated to the efficient pressure determined by its size, and then our unique safety valve takes off the

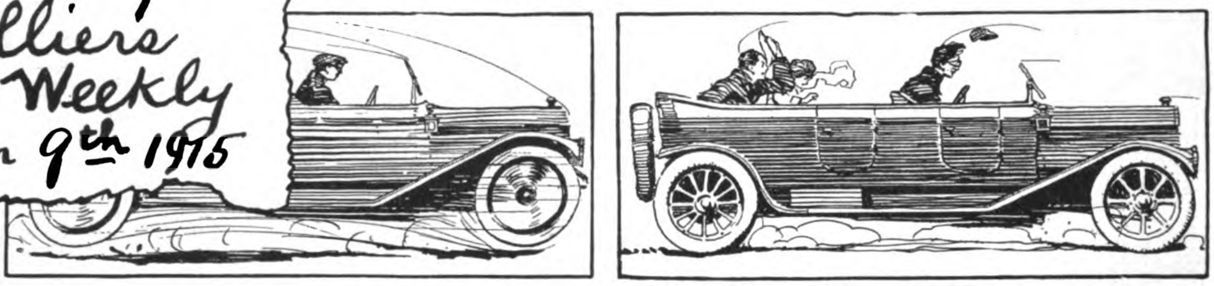
And the Very Next Minute—? ? ? ? ?



A 40 H.P. Engine *versus* What (?) H.P. Brakes?

You *know* your car's *engine* power. But *what* do you know about its *braking* power? Can you swear that your brakes won't fail you in a pinch?

Probably you don't know just how your brakes are lined. Too few drivers do. But for Safety's Sake mark this: if the brake lining on your car gives you less than 100% gripping power, *you flirt with disaster every day you drive.*

Thermoid HYDRAULIC COMPRESSED Brake Lining - 100%

Many automobile owners do not even know that brakes are *lined.* Of those who do, few could tell you what with.

You—and thousands of others—investigate engine power carefully. Axles; tires; extras; lighting and starting systems; all are studied

Every necessity and convenience for putting and keeping the car in *motion* endure your mental acid-test.

Yet most men—perhaps YOU—neglect that all-important factor, brake lining, on which *brake reliability* depends.

Of course it's annoying when your car won't start. But—it is dangerous when it won't *stop!*

* * * * * *

Leading automobile manufacturers protect you to their best ability by equipping with good brake lining. (Thermoid is used on more high-grade cars than all other linings combined.)

But the best brake lining will wear away in time. *Less* than the best loses its friction power long before it is all gone.

You must protect yourself.

When you buy a car, insist that it be Thermoid-equipped. If you have driven your car a time, have the brake lining tested. When it comes to re-lining, demand Thermoid. In that way you can be sure.

* * * * * *

Brake lining, to be 100%, must be brake lining all through. Not merely on the outside. You trust it with your life. Hence, it must be trustworthy to the last.

Thermoid retains its 100% gripping power even until worn *paper-thin.* Hydraulic compression makes it one solid, single substance of uniform density clear through—instead of being loose and stringy (and friction-shy) on the inside, as is ordinary woven brake lining. Cut a piece of each open. You will *see* the difference.

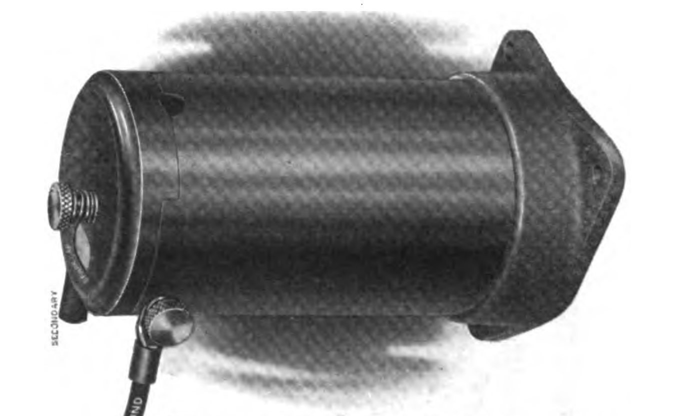
Thermoid cannot be burned out nor destroyed by any heat generated in service. It cannot be affected by oil, water, gasoline, dirt. Its wearing-life is greater. It contains 50% *more* in actual material.

No man knows how many accidents Thermoid might have prevented. We can only urge *you* to guard YOUR safety with Thermoid.

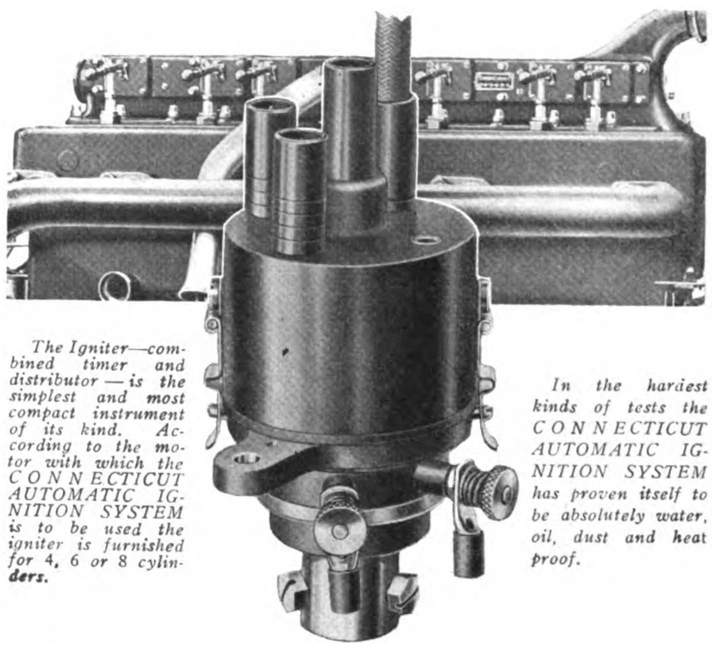
When You Must Stop Your Car, Trust Thermoid.

Thermoid Rubber Company, Trenton, N. J.

Our Guarantee: Thermoid will make good—or we will



This is the transformer coil which carries the primary and secondary windings. While the points in the breaker-box are closed the primary coil is being saturated. When the primary circuit is broken induction sets up a high tension current in the secondary winding.



The Igniter—combined timer and distributor—is the simplest and most compact instrument of its kind. According to the motor with which the CONNECTICUT AUTOMATIC IGNITION SYSTEM is to be used the igniter is furnished for 4, 6 or 8 cylinders.

In the hardest kinds of tests the CONNECTICUT AUTOMATIC IGNITION SYSTEM has proven itself to be absolutely water, oil, dust and heat proof.

The relative superiority of one ignition system over another amounts to very little unless it reveals itself in the performance of the motor, its starting, idling, hill climbing, fast running and in a hundred and one other ways.

The relative superiority of CONNECTICUT AUTOMATIC IGNITION is so conspicuous that the most inexperienced driver feels it at once in the snap and vim it engenders.

any of the others but it tempers its output to meet the needs of your car's motor for every phase of driving.

Connecticut Automatic Ignition includes every advantage of other forms of ignition and is free from the limitations to which other systems are subject.

Little Difference in Cost

So when your car is equipped with this system, and whenever you see the Connecticut Automatic Switch on the dash you can be sure the maker of your car has given you unqualified ignition efficiency.

Why compromise with an inferior equipment when the **difference in cost is so little?**

The ideal adaptation of Connecticut Automatic Ignition is in conjunction with a generator supplying current to a storage battery for lighting and starting.

The Connecticut Automatic Igniter System is fully as great an improvement over the present day magneto as the magneto was over the old-time vibrating coil.

More Effective Spark at High Speed Than Magneto

The Automatic Igniter produces its hottest spark on the slowest speeds whereas the magneto spark is weakest on slow speeds and hottest at high, but even so the Igniter will give a more effective spark on the high speed than the magneto and on medium and low speeds there is no comparison.

Material Saving When Electric Starters Are Used

On cars equipped with electric starters and in fact for any kind of starting, it will be readily appreciated what an advantage the Automatic Igniter with its hot spark will be over any other form of ignition.

When electric starters are used the saving on the Battery will be very material.

Simplest System of Ignition Thus Far Devised

A hot spark is most necessary when throttled down in traffic or otherwise, or when hill climbing with a heavy charge of gas. Under these conditions the difference over the magneto turning over slowly and producing its weakest spark is most noticeable.

It is the simplest system of Ignition thus far devised and can be quickly understood by the average garage man.

No other battery ignition system can approach Connecticut Automatic Ignition in efficiency, for the closed circuit types have the fatal weakness of being unable to protect their ignition source against draining. Mechanical and electrical lag are ever present in relay and instant contact type systems—either or both are fatal to synchronism. This kind of ignition cannot graduate the quality of its sparks to meet conditions of carburetion, starting, slow running, hill climbing, etc.

MERIDEN, CONN.

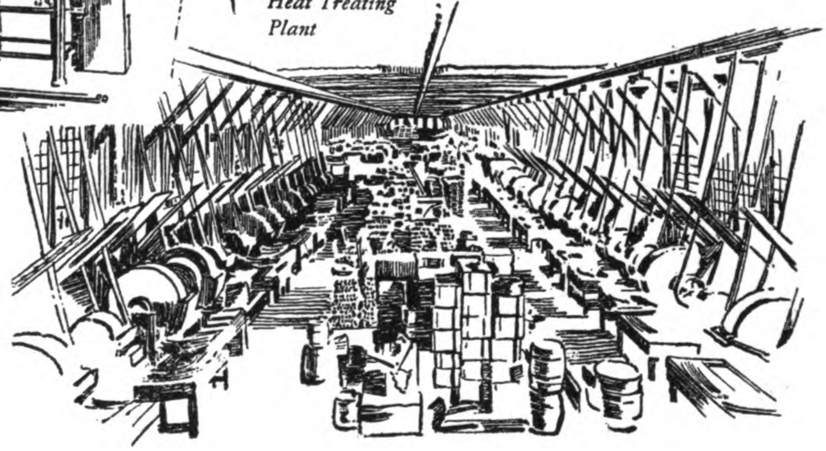
SHELDON

TRADE confidence in a product is the greatest asset any organization can acquire. We have always known this and it is our policy to conserve such an asset. The policy which has been so successful in building up the trade confidence in SHELDON Products as it exists today, will be continued in the future, and with our resources, facilities and organization, we believe that we can not only materially increase the existing prestige of SHELDON Products, but make the name SHELDON a valuable asset to the manufacturer who builds SHELDON Parts into his vehicles and to the dealer who in turn sells the finished vehicles which incorporate one or several of SHELDON Products.

The insurance of quality in SHELDON Products gets its root in the executive branch of our organization.

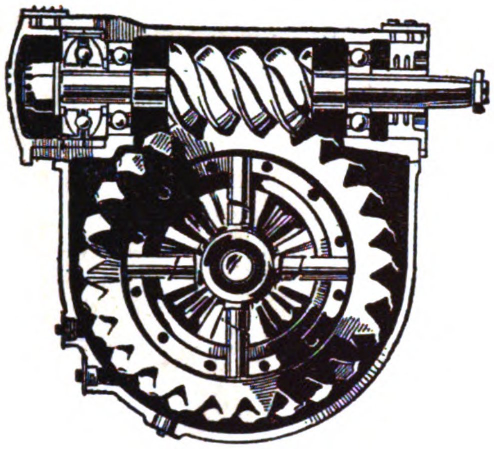
Ours is essentially the product of engineers and the designing, experimental, manufacturing, testing and selling branches of our business are under the direct supervision of a corps of engineering specialists second to none in the world in their skill, experience and practical comprehension of their respective lines.

Corner in Heat Treating Plant



The equipment of the SHELDON AXLE AND SPRING COMPANY'S plants is modern to the last detail.

One Section of Spring Grinding Department



SHEL

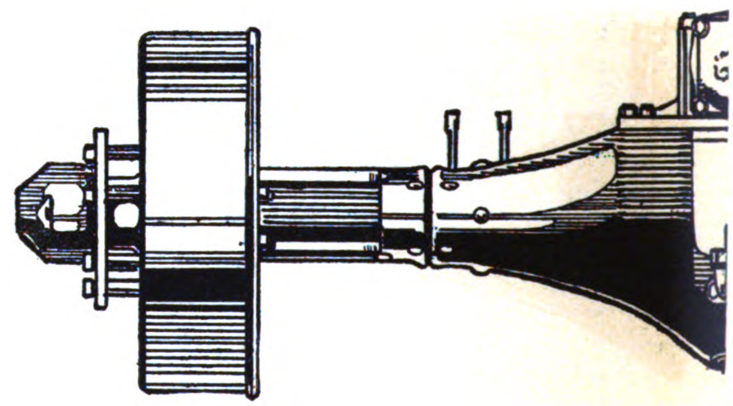
WORM GE

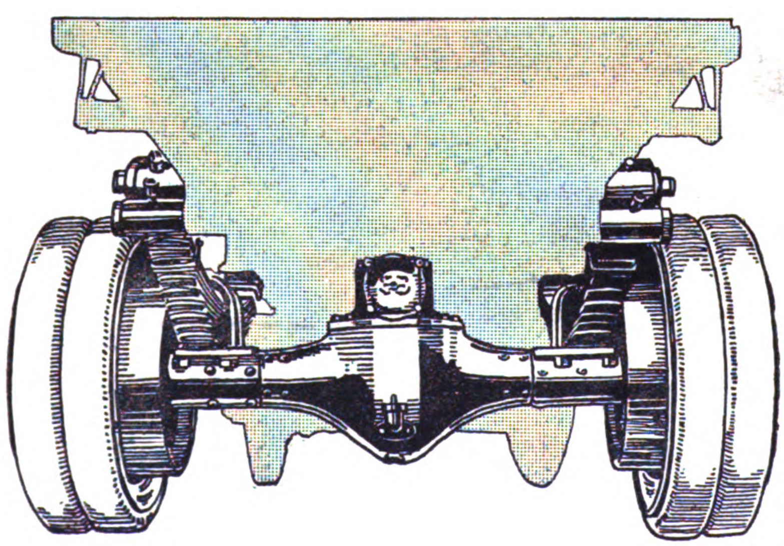
SHELDON'S preference for the worm gear type of axle is based on efficiency of that type of final drive. So thoroughly and so practically have our engineers gone about the design and manufacture of worm gear rear axles that they have produced a type of worm gear drive that transmits to the wheel from 94 to 97% of the power applied.

Efficiency, not manufacturing expediency, dominated our preference for ball bearings to take both radial and thrust loads as they appear in a rear axle.

Our preference for the semi-floating type of axle construction is based upon strength and service alone. We believe, and results have vindicated our judgment, that following the semi-floating principle it is possible to build an axle which makes accessibility an unnecessary factor in the problem.

SHELDON BRAKE AND RADIUS ROD EQUIPMENTS are built to provide the most efficient layout for truck makers who prefer the chain drive to other forms. SHELDON BRAKE AND RADIUS ROD EQUIPMENTS are individual in that they provide for the braking energy to be applied at the rear wheels instead of at the jack shaft. It will be seen readily what an improvement this type of equipment is over the conventional jackshaft brake arrangement.





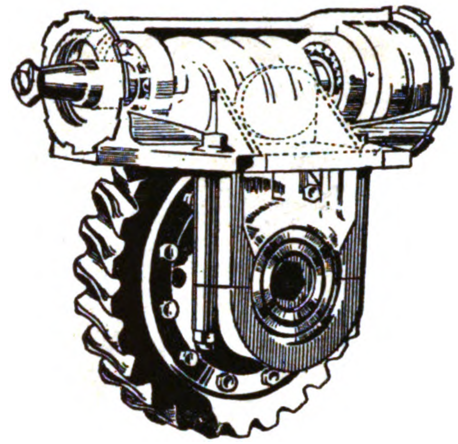
SHELDON TRUCK PARTS are sold only to manufacturers who will agree to use them on trucks with the carrying capacity for which such parts are designed.

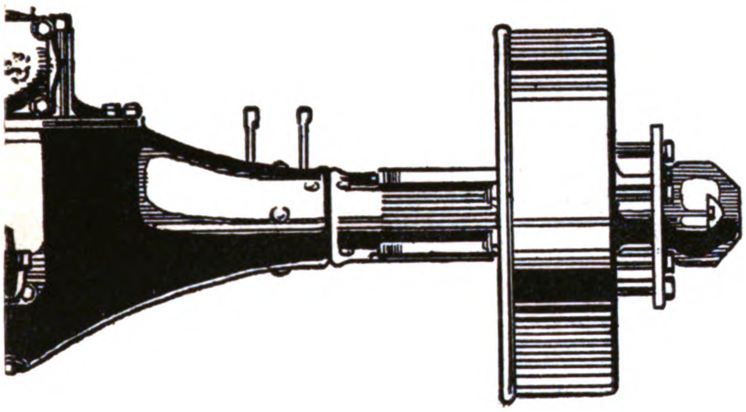
The following clause in our contract and order for automobile axles or other truck parts is a firm foundation upon which the dealer can rely in making statements as to capacity, efficiency and service.

"The buyer agrees to use

,DON

AR AXLES





SHELDON WORM GEAR REAR AXLES are made in all sizes for pleasure cars, and commercial vehicles ranging in capacity from 1500 lbs. upwards of five tons.

SHELDON FRONT AXLES cover the same range of purposes and capacities.

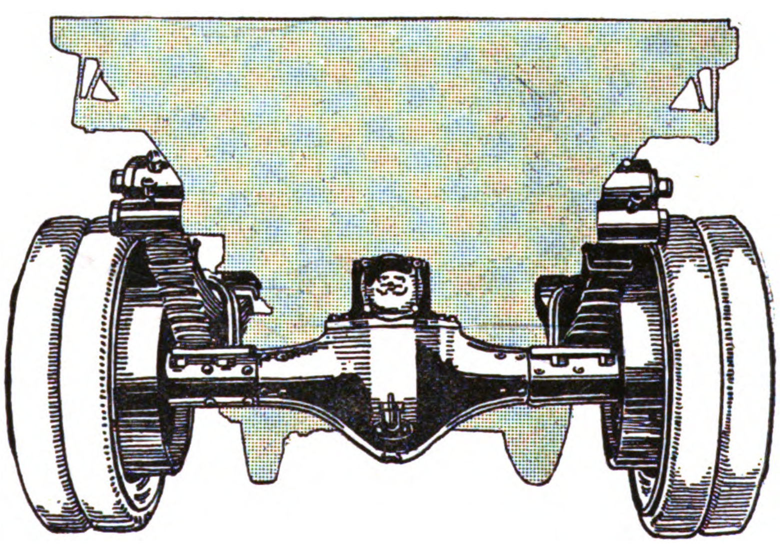
If SHELDON design evidences a preference for certain type of construction, know that no motive other than ultimate efficiency and service governs us.

The selling policy under which SHELDON Products are marketed is one of the fairest and most consistent ever conceived. Primarily it is designed to insure the unqualified satisfaction of motor vehicle manufacturers, dealers and users, and since this policy has been rounded out and put into execution it has proven to be the most economical and effective in every way.

SHELDON Products consist of worm gear rear axles, front axles and springs for trucks and pleasure cars, and brake and radius rod equipments for heavy duty trucks.

While SHELDON WORM GEAR REAR AXLES represent the highest sum of axle essentials and improvements, and while their efficiency is greater than any other known type or make, and while they are designed primarily for American road and load conditions, their finished appearance, clean lines and balance prove beyond question that American Automobile Manufacturers do not have to import parts or equipment when appearance plays any part in the selection of goods.

the material called for in this order on trucks with a carrying capacity as given herein. Any departure from this agreement relieves the seller of all responsibility for breakage, and the seller may at his option discontinue furnishing additional equipment for such trucks."



The result of 22 years' successful experience in building motor cars

THE
HAYNES
America's Greatest "Light Six"

conceded generally as the best car of its type in America today, will be exhibited at the New York and Chicago Automobile Shows.

Three Body Styles

Model 30, America's Greatest "Light Six"—Five-Passenger Touring Car, 121″ Wheelbase, Weight 2950 lbs. $1485

Model 30, The Prettiest Roadster in America.................................. $1485

Model 30, The Haynes "All-Weather" Cabriolet.................................. $1750

In Addition We Offer Model 33

THE KOKOMO "SIX"

a brand new seven-passenger touring car. This model is similar to our Model 30, America's Greatest "Light Six," with the exception that it has six inches more wheelbase, a seven-passenger body, 35x4½" tires and weighs 3050 lbs.

This model will likewise be exhibited at the leading automobile shows and the price will be announced January second at the opening of the New York Show. Deliveries February first.

Detailed specifications and full information concerning unoccupied territory upon request.

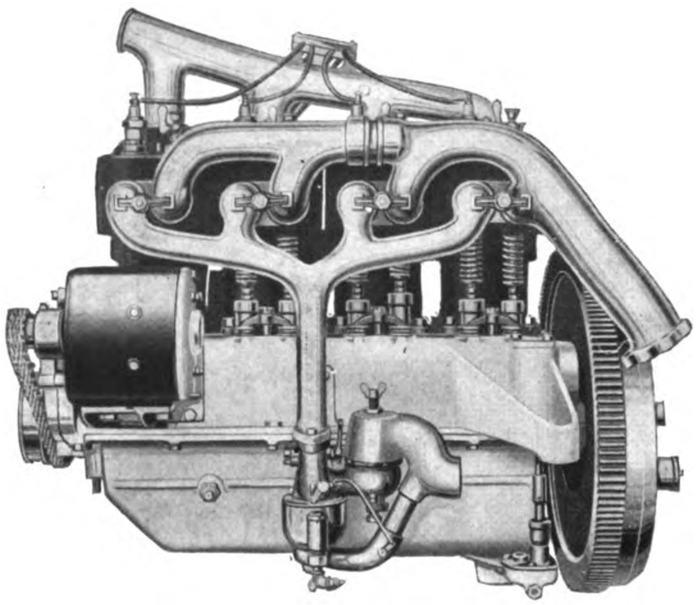
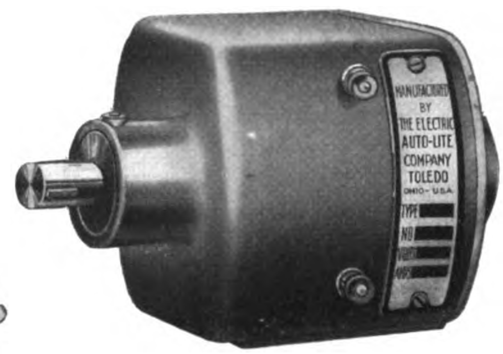
The Perfect Source of Current



The AUTO-LITE G. C. Generator installed on the new Model 80 Overland.



The AUTO-LITE Model G. C. Generator is designed to be driven by either a chain, train of gears or a belt. It runs at 2½ times engine speed, has a maximum output of 14 amperes and produces current at a car speed of less than seven miles per hour.

WHEN you purchase an automobile upon which the AUTO-LITE system is installed, you secure the utmost a car manufacturer can give in electrical equipment. He has spared no expense to provide you with the most perfect source of current that it is possible to build.

The AUTO-LITE generator keeps your battery charged—all the time. At any speed over seven miles per hour it is storing up current for future consumption. It is absolutely automatic in operation and control.

This simple and positive AUTO-LITE method of governing the current output is of great advantage to car owners. It eliminates all troubles from complicated controls.

As Sure-footed as the Mountain Goat!

FOR perfect security in motoring, for assured protection against the dangers of skidding, and for real Extra Service, thousands of motorists pin their faith to

FEDERAL
"RUGGED" TREAD TIRES

The Federal "Rugged" is of much heavier, stronger construction than ordinary non-skid treads and no other is heavier. "Rugged" describes it accurately.

These big, sturdy studs of rubber, broad and thick, won't let your car skid. And from the path of the wheel they deflect many an object that would cut or puncture the tire.

Double-Cable-Base

The exclusive Federal Double-Cable-Base construction positively eliminates rim-cutting, side-wall blowouts just above the rim, tube pinching, and the danger of a tire slipping off the rim.

Federal "Rugged" Tread Casings have been materially reduced in price but the Quality remains absolutely unchanged.

Improved methods of manufacture have lowered our production costs on these famous non-skid casings, and we have turned this saving to the benefit of the motoring public.

Begin using Federal Tires now and take advantage of their Extra Service.

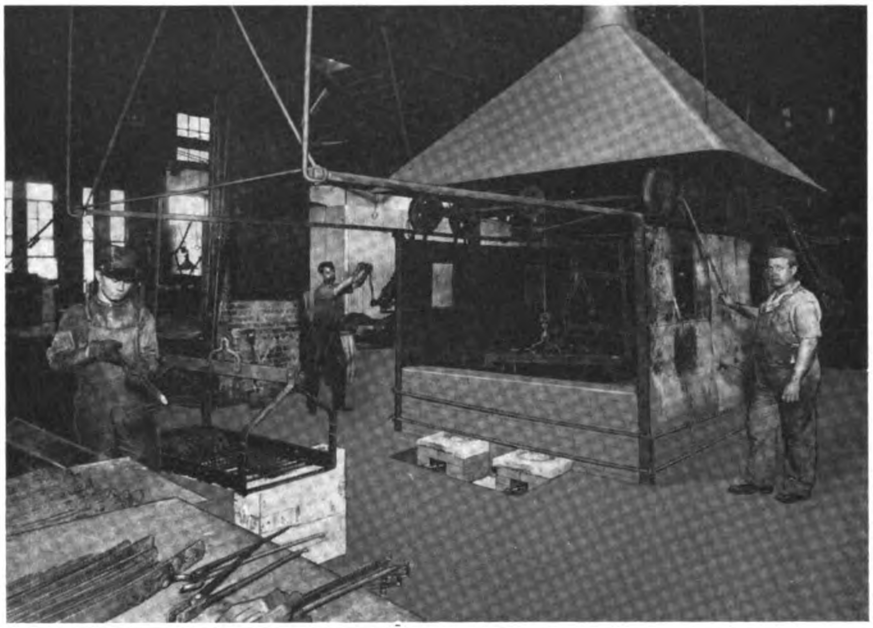
The Strength and Riding Quality of Your Automobile Springs Depend Upon Their Tempering



A View of Chemical Bath in Our Plant

A Uniform Tempering Heat

The old way of tempering a spring was to put it back into the furnace after it had been quenched in oil, which was at a cherry red heat, and leave it until the oil had burned off. Most quenching oils have a flash point between 120° C. and 180° C., and the burning off of the oil only indicated that this temperature had been reached. If the furnace happened to be hotter at one end than the other, that would make one end of the plate softer. On the whole it was all a matter of guess work.

Another way of tempering a spring is to have a special furnace in which the temperature can be regulated for a black heat. However, these furnaces are large and it is impossible to maintain a uniform heat throughout the entire chamber.

The most satisfactory way is the use of a salt bath, as shown in the photograph. This consists of a cast iron tank which contains a mixture of alkali salts. These salts melt at about 300° C. and can be heated to 650° C. The temperature is uniform throughout and evenly tempers the steel. For this method the plates of the spring are placed in a metal basket and spaced so that they do not touch each other at any point. The basket is then lowered into the molten hot salt for a given length of time, depending upon the temper required, thus producing an even temper throughout every plate.

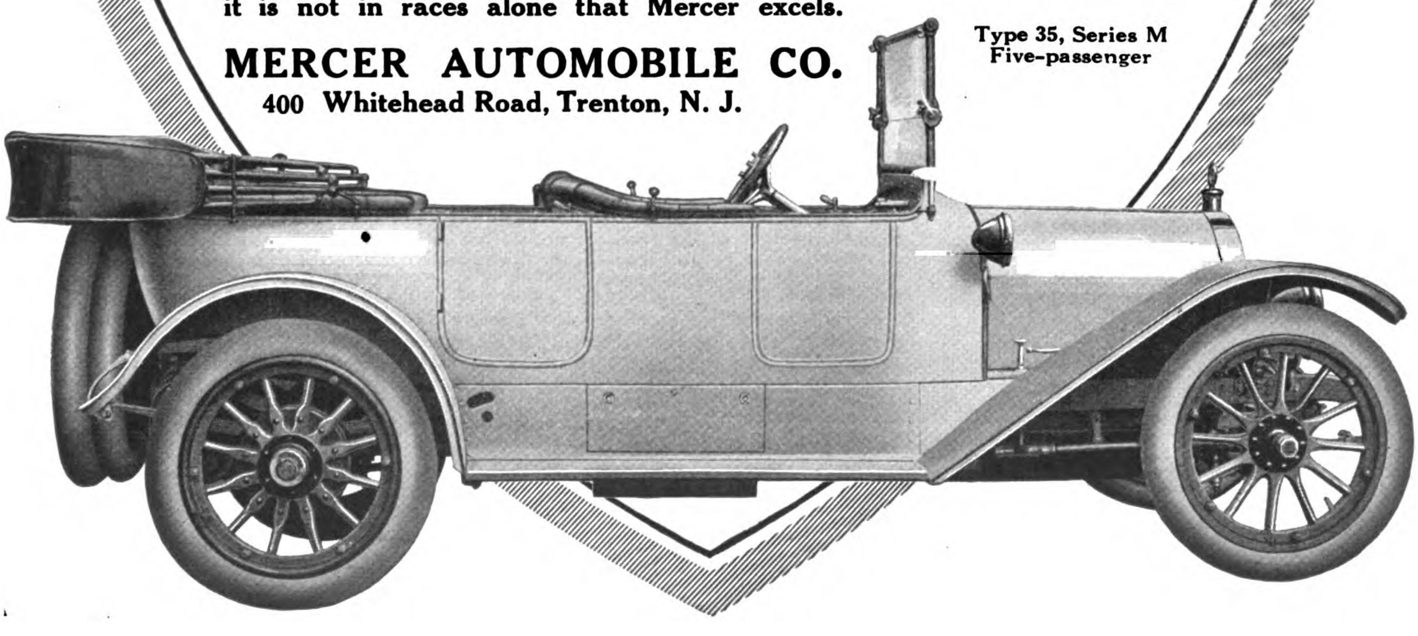
Five-passenger



Thoroughness

We have at times lost business because of our thoroughness, but subsequent evidence has proven that we are not old fashioned, if a little arbitrary. Here is an instance in point. There is about as much sense to the trunnion method of supporting a radiator as there would be in carrying a baby by the ears. This construction places the burden of resisting all of the strain a radiator can be subjected to upon the thin metal sides of its case. In a short time the weight of the radiator multiplied by the jars and jolts of rough going causes the case to pull loose from the tubes or the tubes themselves give way.

This type of construction is entirely at the mercy of the weaving there always is in the side members of a chassis frame. Good engineers know that a radiator which is supported in saddle made of channel steel and bolted to each side frame member is the only correct method of radiator suspension.

In carrying out our policy of thoroughness we will not build radiators for any manufacturer who uses any other method of attachment.

Go to the Automobile Shows determined to see the

Herff-Brooks

Four *and* Six

YOU dealers who are looking for cars that will sell freely because they are big values, will be well repaid by studying the show exhibits of Herff-Brooks cars.

Run down the specifications point by point, from the powerful motors to the well-built rear axles and the complete equipment.

Notice the number of crank-shaft bearings, the power, the high-grade Stromberg carburetor and best Bosch ignition. Observe the Timken and New Departure bearings, the electric installation, the high-grade accessories, the complete equipment.

Frankly, such cars would be impossible at the prices if we did not build them complete in one huge factory where, for special reasons, overhead costs are very low. No car in the world is more completely manufactured in one plant than is the Herff-Brooks.

There will be much to see at the shows, but the one thing no dealer should miss is the Herff-Brooks exhibit.

Look at these specifications

THE CHAMPION PRIM

VITALIZES COLD M

Start Your Motor on the First Quarter Turn

An important new feature on the 1915 Champion Priming Plug. A key lock is supplied with each plug, right on the needle valve—always in place, ready for use.

With this key lock it is the simplest thing in the world to open the needle valve, prime, and then close the valve so tightly that there is absolutely no chance for loss of compression.

Champion Priming Plugs are not an experiment. They are not a freakish idea, placed upon the market one year, and then—never again. Champion Priming Plugs have been on the market for the past four years. They have been a success from the start.

Champion Priming Plugs are **built with the same care and manufacturing methods which are used in the manufacture of all Champion Plugs.** In fact, **the Champion Priming Plug is simply a tried and proven Champion Spark Plug which has the additional feature of a truly efficient priming device.**

HOW TO OPERATE. **Simply turn the needle valve in the Champion Priming Plug, inject a few drops of gasoline which flows directly to the sparking point. Tighten the valve.** Touch the starting button, or give a pull on the crank and "away she goes." You don't even have to remove your gloves, or use a wrench. The key lock on the needle valve makes this unnecessary.

CAUTION. Beware of all Petcock type priming plugs with leaky petcocks.

TOLEDO MADE FOR THE

NG CUP PLUG

OTORS

A Few Cold Weather Don'ts

DON'T crank your head off

DON'T exhaust your storage batteries trying to start.

DON'T laboriously remove spark plugs in order to prime your motor.

DON'T depend on petcocks in your motor. Gasoline must be brought direct to the sparking points.

DON'T send for mechanician to start your car.

DON'T be towed home on account of inability to start.

DON'T forget when you are buying a set of priming plugs that you still want ignition. Insist upon the CHAMPION Priming Plug, the only plug made with a needle attachment for priming. Easiest to operate. Needle valve never opens from vibration. Absolutely no possibility of loss of compression.

CHAMPION Priming Plugs are made by the largest manufacturers of spark plugs in the world, the makers of CHAMPION Spark Plugs, which are the factory equipment of over 75 per cent. of all the automobiles made in this country. Here is made every piece that enters into the construction of CHAMPION Spark Plugs—every nut, every center wire, every bushing, every shell, every gasket, every part is carefully wrought from the raw material. Even our porcelain cores are made in our own porcelain factory.

STRONGEST GUARANTEE EVER MADE: Complete satisfaction to the user, or free replacement, repair, or your money back.

Insist upon CHAMPION—the needle valve type of Priming Plug. Made in all sizes to fit any motor.

WHOLE WORLD'S TRADE

Everlastingly Good

MOTOR NECESSITIES

Here are a few of the new "Everlastingly Good" Motor Necessities to be introduced at the Automobile Shows.

Each item produced by us represents the highest mechanical skill in production and has been carefully designed to efficiently fill the place for which it is designed.

This page offers no space even for a small portion of our entire line and few of the details of design, workmanship and finish can be brought out. "Everlastingly Good" motor necessities insure satisfaction to both user and dealer. Send for 1915 catalog and dealers' discount sheet. It represents the most up-to-date and complete line of accessories produced.

Red Head

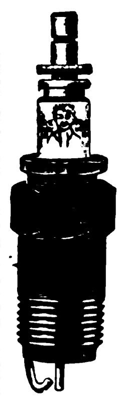
1915 SPARK PLUGS

REGULAR—This Plug is the proven master of any motor up to 40 H. P. Five years on the market; millions in successful use. It has a straight-sided porcelain that "laughs at the heat"—guaranteed not to crack from the heat of the motor.

Highest grade imported Meteor wire sparking points. The cap and center electrode are integral with the porcelain, and the core can be removed without unscrewing plug from the cylinder. All joints are absolutely gas-tight—proof against loss of compression.

They are made in all threads—porcelain or mica. The F. O. R. M. S. plug is specially designed for the engines of the Ford, Overland, Reo, Maxwell and Studebaker. Price $.75 each

REGULAR ⅞ Inch



F.O.R.M.S. ½ Inch

PRIMING—Has big straight-sided porcelain — guaranteed not to crack from the heat of the motor and almost indestructible; big steel bushing; long body shell — overcomes the depression in the cylinder head and the nut; big priming cup; heavy meteor wire firing points; oil drip bend; lower (petticoat) end of the porcelain with two insulating surfaces; expansive firing chamber; threaded stem sunk and baked into the porcelain — cannot be twisted or broken off when tightening the terminal.

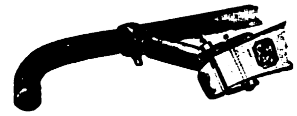
Price $1.25

PRIMING

BIG BOY — For high duty motors—where there is also an intense spark — where the regular plug is unequal to the strain—use the RED HEAD Big Boy. Has a big indestructible porcelain, a big steel bushing with wide gripping surfaces, a heavy non-burning nickel steel center electrode; three heavy nickel steel firing points, bent to provide a flow for the oil and flattened at the ends to insure a big spark. Carries an unlimited guarantee.

Price $1.00

BIG BOY



The "E. G." Frameline Bumper

This neat bumper is designed especially to equip Cadillac, Overland, Oakland, Winton, Studebaker, Cole, Mitchell, Buick, Hupmobile, Chalmers, National, Jeffery, Peerless and other cars. It is clamped to the top of the frame by an adjustable clip and yoke.

Price, finished in nickel.......... $9.00

"E. G." Adjustable Channel Bumper

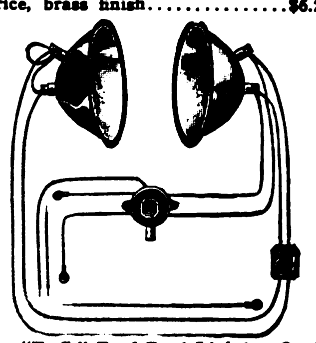
This bumper is designed to fit any car with a channel frame and is attached with forged hook bolts clamping the flanges of the frame. Fitted with stiff steel spiral springs concealed in telescopic tubes, to afford shock absorption.

Price, complete.................. $7.85

"E. G." Ford Clamp-on Bumper

This is the neatest, lightest and strongest Ford bumper on the market. It clamps on; no drilling. Original design which gives the Ford the appearance of a car with a drop frame.

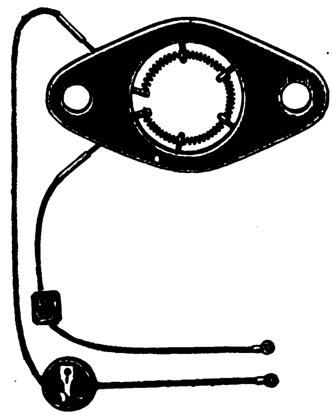
Price, brass finish............... $6.25



The "E. G." Ford Dual Lighting Outfit

Headlights connected to the magneto give illumination only when the car is running. This outfit provides for an additional 2 c. p. 3 V. bulb in each reflector which connect with dry cells and give light when the car is standing. Can also be wired up for electric tail light.

Outfit, complete, with 5-pt. switch, $5.60 to $6.15, according to size and finish.



The "E. G." Ford Vaporizer

This device heats the charge as it is sucked out of the carburetor causing it to vaporize and rise through the manifold into the cylinders. While simple and inexpensive, it is positive and efficient in its operation and insures a quick start in cold weather. Can be installed in a few minutes by anyone. Furnished complete, with wires cut to length, terminals and switch attached.

Price, ready to install............ $2.00

The "E. G." Lighting Control and Dimming Switch

With this switch you can dim the lights without stopping or leaving the car. It is the only logical solution for overcoming the glare of the headlights. With each switch wiring diagrams are included, giving three different methods of wiring. The case and cover is of hard rubber and metal parts are brass stampings.

Price, complete $1.50
(Special design for Fords.)

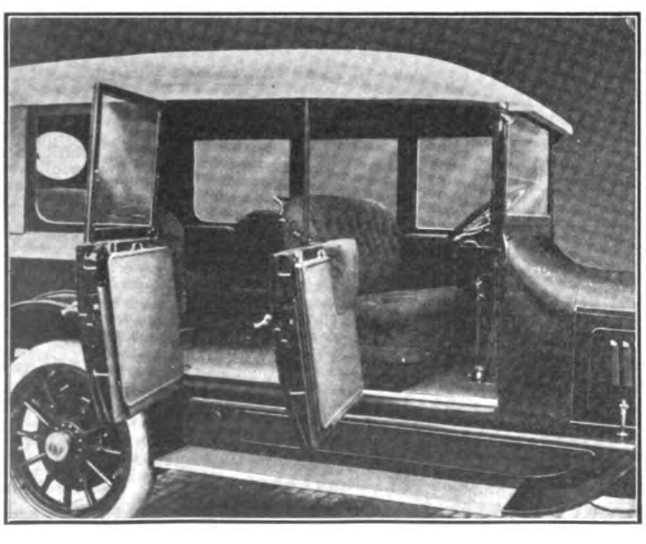
Bush Terminal, Model Factory No. 20, Brooklyn (New York City)

Will Exhibit at the Automobile Show, Grand Central Palace, New York, January 2d to 9th. Spaces D117, 118, 119 — Fourth Floor



The Springfield Metal Body Exhibit at the New York Automobile Show, January 2nd-9th, is one no dealer can afford to miss.

Your purpose in attending the Show, is one of inspection, comparison and formulation of ideas as to the relative values offered.

Our purpose in exhibiting the various forms of Springfield Convertible and Demi-Convertible Bodies is to convince you of the practical merits of Springfield Bodies and the opportunity they offer you, not only to make money, but to ***enable you to sell your customers a car infinitely better adapted to their requirements and pockets as well.***

FEDDERS RADIATORS
f
ACHIEV
Quantity at no Sa
Fedders Quality is the result of fifteen years of specialized experience.
Fedders design as it stands today is not urged on automobile manufacturers so much as it is recommended as a criterion of style, efficiency and construction to guide them toward perfection in one of the most important details of their cars' equipment.

FEDDERS
RADIATORS
EMENT
crifice to Quality
Fedders facilities, both in shop equipment and in organization, have been developed to such a state of perfection that the automobile industry finds radiator quality reconciled with quantity production—a circumstance which works to the greatest good of the greatest number.

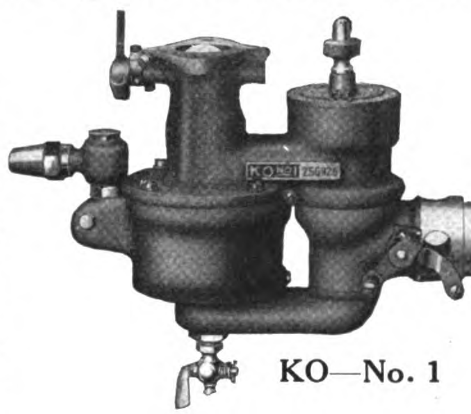
FIVE GREAT World Records

The new Stromberg Carburetors have been doing things. They have been making world records in tests which have been officially observed by such men as F. E. Edwards, technical representative of the contest board of the American Automobile Association. Each and every one of the five great records shown in this advertisement is enough to convince you that these new Stromberg Carburetors are the best on the market.

There are records in Gasoline Economy, Power, Acceleration, Flexibility. Each telling and proving conclusively of the wonderful performance of the new Stromberg Carburetors. Read the reports:

Jeffery Six

In an official test this car, which with five passengers, weighed 4100 pounds, equipped with a new Stromberg Carburetor, made the remarkable record of 28.7 miles on 1 gal. of gasoline, or 58.8 ton miles.



KO—No. 1

Overland 80

Carrying five passengers, total weight 3930 lbs., this car equipped with a new Stromberg Carburetor in an official A. A. A. test, with 1 gallon of gasoline, went 29 miles or 56.9 ton miles.

Speed With Marmon Model 41

The wonderful speed test made on the Marmon Model 41 at Indianapolis was made possible by the fact that the car was Stromberg equipped. During this test the car, with top and wind-shield up, carrying five passengers, made the remarkable record of *62.89 miles in sixty minutes* on Gasoline.

Record Hill Climbing Test

in 60 Minutes
Constant Running
Marmon Small Six

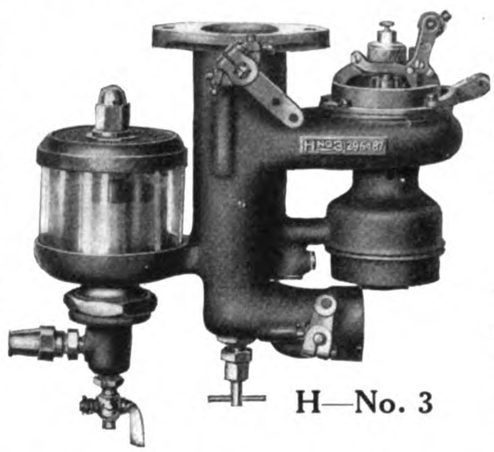
Demand More of Your New Car

You have no idea what a difference the equipping of your car with a new STROMBERG CARBURETOR will make. It will produce a great saving in your gasoline bills, for you will get more and better miles for each gallon you use. This carburetor will insure you a quick get-a-way giving you all the power that any one can desire without sacrificing in the least any of the other requisites of a perfect instrument.

All these tests were made when the temperature was low—in cold weather—under most unfavorable conditions. They indicate what one of the new Stromberg Carburetors will do on your car.

Haynes Light Six

Equipped with a new model Stromberg demonstrated its power in the Pittsburg hill district. It climbed hills on high without overheating. With car and passengers weighing 4390 lbs. running from 2 M. P. H. in high gear it was speeded up to 42 M. P. H. in 200 feet.



H—No. 3

Cole Touring Car

Four cylinder stock car carrying seven passengers, which with the car weighing 4390 lbs. and being equipped with a new Stromberg Carburetor, traveled 24.135 miles on one gallon of gasoline. In thirty minutes speed test this car averaged 55.63 miles per hour.

See This Wonderful Carburetor at Grand Central Palace New York, Auto Show January 2nd to 9th, 1915

We'll have a full display of the new Stromberg Models at the New York Auto Show—to be held in the Grand Central Palace from January 2nd to 9th, 1915. Drop in and we'll tell you which Model Stromberg will get most out of your car. If you don't come to the Show, send for literature.

Brush Holder Assembly

Granting that you fully appreciate the value of a single unit electric starting and lighting system that always can be depended upon to furnish ample power for both starting and lighting—that positively and automatically prevents you from ever stalling your motor—that is small and compact, so much so that it weighs only 45 pounds—

Granting that you are cognizant of the advantage of having such a personification of efficiency and dependability as a part of your motor car, think now of this further all-important feature.

This is the plus value

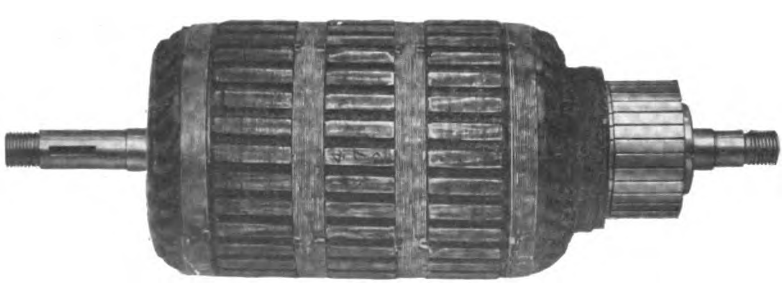
The Dyneto single unit electric starting and lighting system will more than likely outlast any car upon which it is installed.

Because of the unique design which provides for the elimination of all complications and wearing parts such as cut-outs, relays, solenoids, clutches, gears, etc.—because of the use of only the very finest and most expensive materials in its construction—because of the utmost care in the machining and manufacturing of each and every part that goes to make up the finished unit—because of the insistence of this care in manufacture by most exhaustive tests and inspection of each and every operation, singly and in assembly—

The Dyneto single unit electric starting and lighting system will stand up and perform to its fullest efficiency long after most other parts of the car upon which it is installed have required repair or replacement. About the only parts of the Dyneto that will show any wear at all are the brushes and we have made any number of tests which indicate that those brushes will stand up for as much as 100,000 miles.

Almost nothing to wear

Armature Assembly



Quality Always Present

Just as prima facie evidence of the truth of these past statements, herewith are a few details.

Wherever it is possible to use stampings instead of cheaper castings, stampings are to be found in the Dyneto. The shaft is made of the finest and most expensive alloy steel specially heat treated, when a cheaper and inferior substitute might easily be used without detection till months after the system had been sold. The commutator segments not only are of special design to prevent wear, but they are made under a special process to insure hardness. In addition to this the copper used is the purest and highest grade obtainable. Dyneto brushes not only cost more as bought by us in bulk, but each brush is carefully examined and tested before it is assembled. And to insure full efficiency out of this exceptionally high value material the tools and dies with which these materials are machined are specially designed and specially produced.

Basic Design Unique

And with this supremacy of design, materials, and construction which assures maximum efficiency, maximum dependability, maximum durability, the Dyneto is comparatively lower in price than most other starting and lighting systems on the market.

This condition is the result of our design purely. The trouble breeding complications of all other systems not only emphasize the superiority of the Dyneto but by their costliness they place the cost of the other systems comparatively above the cost of the Dyneto.

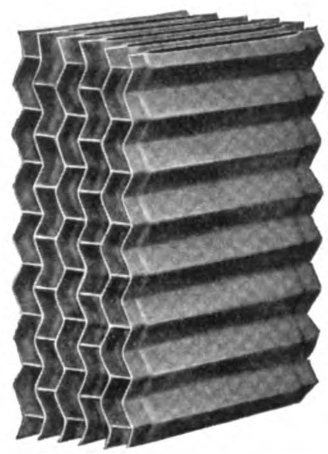
MADE IN DETROIT USA

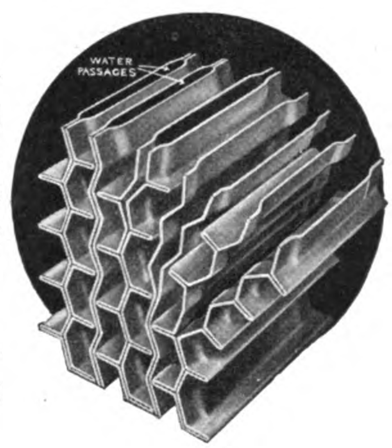
NATIONAL RADIATORS

MADE IN DETROIT USA



THE NEW NATIONAL RADIATOR upsets all precedents in radiator construction. Study the illustration for a moment and you will see why the NATIONAL RADIATOR gives greater strength, bigger cooling surface and uses less water than any other.

An Entirely New Principle of Construction



Made of continuous bands of brass, not built up cell by cell but made as a unit. Radiator leakage is not caused by rust, neither do the tubes burst from over-pressure. The continuous racking strains and jars of the road are alone responsible and surely in time cause the ordinary tubes to pull apart.

The special corrugated construction of the NATIONAL RADIATOR is a natural shock absorber, making the Radiator practically everlasting.

Both air and water tubes are exceptionally large, thus insuring free circulation and greatly increased cooling capacity.

All NATIONAL RADIATORS are tested at not less than fifteen pounds air pressure under water.

THE NATIONAL CAN COMPANY

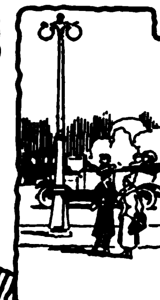
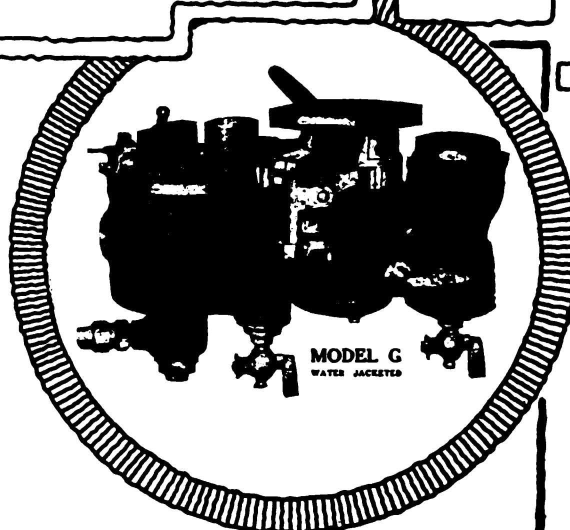
RAYFIELD CARBURETORS



Getting the best in carburetors



WHEN an automobile maker adopts the Rayfield carburetor as standard equipment, he does so simply because he wants the best, and is willing to pay for it.

And generally, you will notice, Rayfield equipment is advertised by the cars that use it, because most people know that the Rayfield is the best carburetor on the market and naturally have confidence in the car manufacturer who uses it.

After all, compared to the selling advantage given a car equipped with a Rayfield and the much increased efficiency of the motor, what does the slight extra cost of the Rayfield amount to? The owner of a car with Rayfield equipment will save in gasoline alone in the first two months' driving more than enough to make up its slightly greater initial cost to the manufacturer.

For every type of car, from the smallest to the largest, the Rayfield is absolutely guaranteed to save 10% to 50% in fuel and on all other points to exceed the performance of any other carburetor.

No matter what car you drive, you ought to have a Rayfield on it.

Stewart

Stewart Owners Buy More Stewarts

—because Stewart trucks, by paying for themselves in a year, are a good business investment.

—because Stewart trucks stand up under the hardest usage.

—because Stewart trucks mean big profits by making money for owners, saving time and bringing trade.

—because Stewart trucks are designed right; constructed right, and built of finest materials.

—because Stewart trucks are simple in design and simple to drive.

—because comparisons show that Stewart trucks cost less to operate than any other delivery trucks made.

—because Stewart trucks show an average annual repair expense of only $1.37 per truck.

—because Stewart trucks do the work for which larger trucks were formerly thought necessary.

These are reasons why Stewart owners never go back to other makes of delivery trucks.

These are reasons why among Stewart owners—and they are to be found in 120 cities and 85 lines of business—there is today *not a single dissatisfied user.*

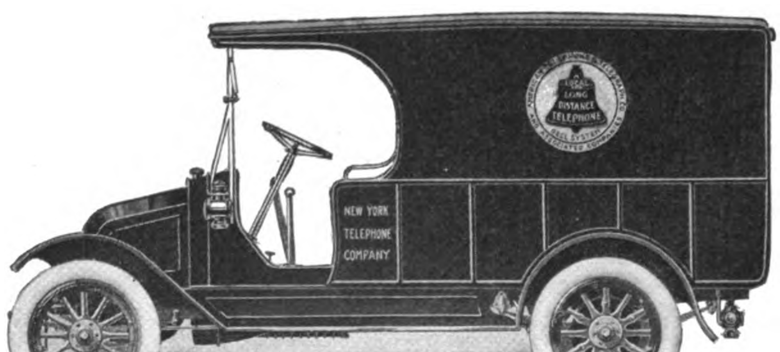
And these are reasons why Stewart owners buy more and more Stewart trucks all the time.

Not only do owners endorse Stewart trucks by first choice and by reorders. Engineers—mechanical experts of high repute—tell us that Stewart trucks are *right*. Not one of them has ever pointed to any feature of the Stewart that needs to be improved.

That Stewart trucks make good and win the confidence of owners everywhere is only natural. For Stewart trucks are built by specialists. All our facilities, all our energy, and the experience of an expert organization have been *concentrated* for five years on this type of delivery truck.

Write *today* for our book, "How Motor Delivery Pays." It contains much information of interest to every business man and every business house with goods to deliver.

Stewart Motor Corporation, Buffalo, N. Y.



Dealers: Ask About Our New Policy

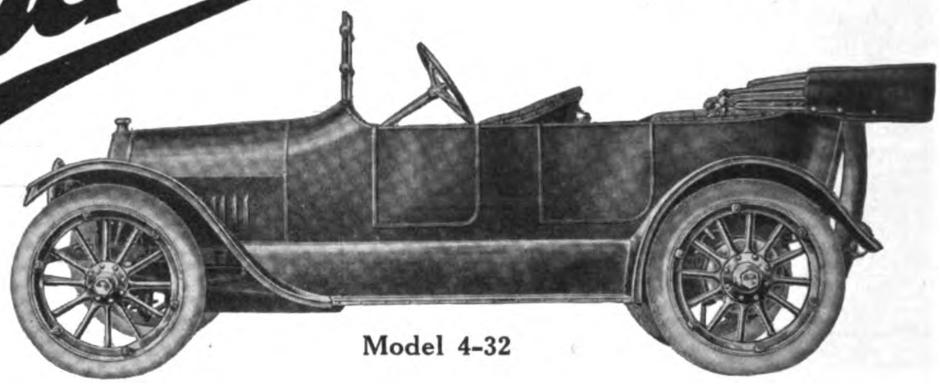
We have a dealership proposition that is unusually liberal. We can assure more prompt deliveries, by reason of increased facilities and larger output. And we do not require dealers to put up a lot of deposit money, nor to contract for a big number of trucks.

Write today and learn about the Stewart proposition—and why it will be to your advantage to handle the Stewart; providing, of course, your territory is now open.

Paterson

Four Cylinder, Long stroke Motor, Delco Starting and Lighting System,

$1095



Model 4-32

To the Man Who Sells Motor Cars

The PATERSON line of motor cars is the line with the VALUE, STYLE and FINISH, made in Flint, Mich., by W. A. Paterson Company, one of the strongest organizations in the business, who have had forty years' experience in the manufacturing industry.

The PATERSON car for 1915 represents the total and combined knowledge of the best and most carefully trained engineers in the automobile industry. This statement is proven by the fact that PATERSON QUALITY reflects the combined buying powers that compose the acknowledged leaders of the automobile world.

Our Four and Six cylinder cars are fitted with NORTHWAY long stroke motors, Weston-Mott full floating demountable rear axles, Delco Single Unit Starting and Lighting system, Stromberg carburetors, One-Man Top, and other high grade units installed and applied the PATERSON way.

We are soliciting the business of distributors in the different automobile centers, who have an established trade, and a line of agents that can and will push a standardized line of automobiles that have the VALUE, STYLE and FINISH.

Our distributors' proposition is an attractive one, and our local agency contract deal will interest any high class dealer that desires to handle a line that will help him in building up a trade that will increase from year to year and stay with him.

Connersville, Ind., U. S. A.

MAKE WINTER DRIVING A PLEASURE

Ieco STEER WARMS

Don't Suffer from Cold

STEER WARMS make winter driving safe. Protect the driver from catching cold. Save cost on winter gloves. Are indispensable to motor truck drivers.

STEER WARMS are electrically heated, leather covered grips that lace on the steering wheel. These neat devices are heated by current from either storage battery, dry cell or magneto. On Ford cars they are connected to the magneto.

STEER WARMS take only half the current of electric headlights and will not damage your storage battery. They deliver the heat to the fingers where it does the most good, keeping the hands and body warm on the coldest, rawest day.

STEER WARMS are easily attached. Will fit any car. No bolts or screws—no holes to bore. Lace on—wire up—that's all. They are guaranteed to give satisfaction—money back if they do not.

Price Steer warms for any car, $7.50 per pair complete; Special Steer Warms for Ford Cars, $5.00.

Sent postpaid complete, ready to attach, upon receipt of price, or C. O. D. if desired.

Dealers These are quick sellers. Every owner wants a set. Guaranteed. We stand back of you. Get your share of the business. Write for discounts.

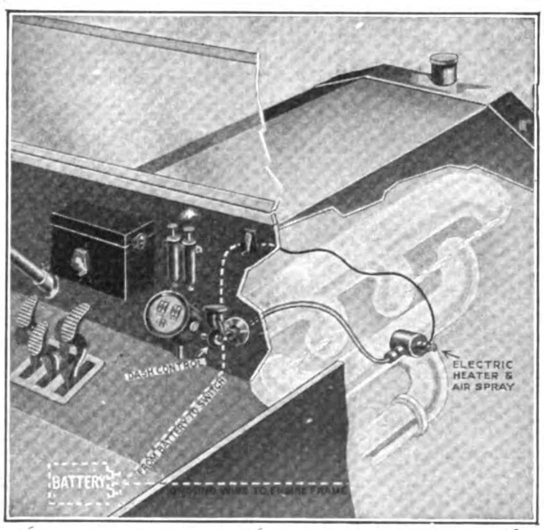
INEXPENSIVE

GUARANTEED



Eliminate Your Starting Troubles with IECO MANIFOLD PLUG

THE IECO MANIFOLD PLUG due to its ELECTRICALLY HEATED COIL, is guaranteed to start your car on the coldest winter day as easily as you can start on the hottest day in summer.

Tests your carburetor at any time regarding quality of mixture.

Keeps your cylinders free of carbon by using a little kerosene through the priming cup.

In addition to eliminating your starting troubles in winter and increasing the power and speed of your car while running, the IECO MANIFOLD PLUG will actually save you within three months the price of the plug in a reduced gasoline bill. The intelligent automobilist will immediately take advantage of this proposition.

The Manifold Plug has an ELECTRICALLY HEATED coil on the inside of the plug that actually boils and vaporizes the gasoline and does not depend upon superficial spraying, which is poor, to say the least, in cold weather. Besides, the vapor enters the manifold near the cylinders and cannot condense before being drawn into the engine.

Price for any car $5.00 complete and ready to install. Current is taken from either dry cells or storage battery.

Sent postpaid on receipt of price or C. O. D. Parcel Post on receipt of order.

This is the
Day of the
Continental
CONTINENTAL MOTORS
Powerful
as the
Nation

123 manufacturers have seen the light; 123 leading makes of motor cars—pleasure and commercial—now take their motion from the Continental Motor; 123—where a year ago there were 60!

Such a growth is profoundly significant. It marks a positive conviction that Continental Certainty is now fundamental in the structure of motor cars whose makers are striving hardest to reach the goal of perfection.

Continental Motors

It marks the final establishment of a definite quality basis in manufacturing—assuring a permanent market for the maker, and a permanent guarantee of goodness for the owner.

The trend toward this standardization has been slow but steady. For twelve years Continental Motors have been leading the way.

Scores of makers knew the overwhelming advantages of a Standard Motor, from both the production and the sales standpoint. They only awaited the right motor, a motor of known quality and national reputation.

Now they have it in the Continental—have a motor proved by time, endorsed by more than a hundred thousand drivers, known favorably to every dealer in the land.

This is the reason for the landslide Continental-ward.

For the manufacturer who today builds into his product a Continental Motor, builds in also an added prestige that carries tremendous advantage for maker, dealer and owner.

This is the day of the Continental—broad sunlight of well-earned reputation, shining into every nook and corner of motordom.

Get into the flood of light. Get your place in the sun.

CC SHOCK ABSORBER

Our 40 Years' Manufacturing Experience and Reputation Stand Back of This New Product

¾ Actual Size

The C-C Shock Absorber is not a makeshift nor the result of an impulse. It is a development and a refinement of manufacturing conditions.

It is just as real, just as efficient and just as high quality as any shock absorber ever produced at any price, notwithstanding the fact that it is made to sell for $8.00 for a set of four.

Just as the Ford Company has been able to continuously and materially reduce the cost of its car by increasing its production and by the installation of manufacturing refinements, just so have we been able to reduce the cost of shock absorbers until we have today a real Ford Shock Absorber made to sell at a price commensurate with the original cost of the car.

Unless your Ford is operated at the minimum of cost and the maximum of comfort and efficiency you are not getting all that the Ford can be made to give you. You have frequently realized that the use of an efficient shock absorber would greatly increase your Ford satisfaction but the price heretofore has been too great.

Now as a result of this 40 years of manufacturing experience, five years of which have been devoted to the problem of shock absorption, we have been able to produce the C-C and at a price you will not hesitate to pay.

Go to your dealer today, have him show you the C-C, its simplicity and sturdiness and have him explain its principle.

When you do this you will take a set of four and have them attached while you wait. It only takes half an hour.

8⁰⁰ for set of four

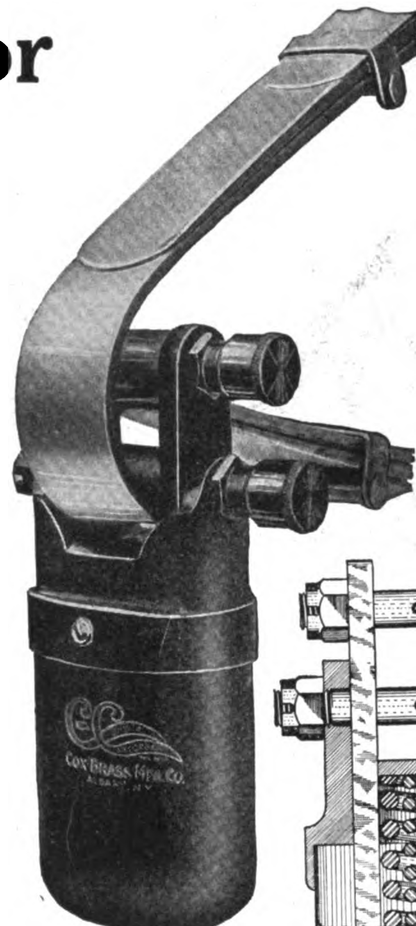
C-C SHOCK ABSORBER

"The New C-C for Any Car"



regardless of the kind you own, offers you through its use a degree of comfort and economy hitherto possible only by an investment of at least five times the price of the C-C.

The new universal C-C is the masterpiece of shock absorption construction. It is our supreme effort after 40 years of manufacturing experience and we are proud to put the Cox trade mark (the guarantee of absolute satisfaction) upon it.

The new C-C is a sturdy, husky shock absorber designed to take care of the jolts and jars suffered by the heaviest of cars. We would not hesitate to recommend it for use on a limousine weighing two and a half tons, so certain are we that it will stand up to its work, even in that event. Note the triple spring construction as shown in the line cut herewith. That's only one of the many reasons for the superiority of the C-C.

No longer need you sacrifice your car and your comfort for the new C-C at $10.00 will serve you and your car satisfactorily as long as your car will last.

Go to your dealer to-day and have him attach a set of C-C's and you'll swear you have a new car.

DEALERS: Think what the Cox line means to you, the C-C for the Ford for $8.00 and the C-C for any car for $10.00. No longer is it necessary for you to carry in stock a dozen different sizes of shock absorbers to meet the varying calls from the different type car owners. The new C-C with an occasional spring change (that you can make yourself) will fit 95 per cent. of the cars on the road to-day.

Write us to-day for our dealers' terms. They're mighty attractive.

Absolutely complete from electric self-starting and lighting system to electric door locks.

FINISH

Finest possible, both as regards upholstery, instruments, dash equipment and body finish.

DETAILS

Body—Streamline, torpedo stern, highest grade blue-black finish, domed fenders. Upholstery, finest quality long-grain buffed leather. Cowl dash instruments; sight feed oiler, lighting and dimming switches, starting strangler, starting and ignition switch, flush type speedometer, generator indicator, shroud light and foot space light.

WHEELS

Five Houk, triple-laced detachable wire, 30x3½ inches, wide hubs.

AXLE

Rear, full-floating, annular bearings throughout. Bevel drive. Ball bearing, universal joints on the Kardan shaft. All gears and shafts 3½% nickel steel. Drive shaft tubular.

New Year

The Spirit of the New Year is for better things.

The world builds on the progress of the past; each new idea, a step; each year, an epoch.

With each succeeding twelve-month of motor car progress comes greater demand for new comfort, further luxury, and more complete appointment.

SCRIPPS-BOOTH luxurious light cars offer in mechanism, the newest engineering ideas of comfort-efficiency; in appointments and interior, the newest standard of luxurious equipment; in road performance, the highest possible standard of riding comfort; and in detail, show a consistent betterment of past motor car efforts, which expresses in itself the very spirit of the New Year.

SPECIFICATIONS:

MOTOR

Sterling, valve-in-head type, high speed, gearset in unit, pump feed oiling with sight feed on dash, 2⅞ bore, 4-inch stroke, four-cylinder, water cooled. Develops 18 horsepower. Fitted with Zenith carbureter and Atwater-Kent automatic spark advance, connected with starter generator system.

STARTING

Bijur single unit electric, connected by silent chain, operated by locking dash switch.

SPRINGS

Front, semi-elliptic with over-slung frame. Rear, floating cantilever.

EQUIPMENT

Silk mohair top with side curtains, rain vision plate glass windshield, electric door lock, Klaxet horn, full tool equipment, jack. Luggage space at the rear large enough for two suit-cases and tools. Spare Houk wheel, tire and tube on all cars.

FEATURES

Klaxet button in center of steering wheel cannot be operated when ignition switch is off, eliminating miscellaneous horn blowing while the car is standing. No projecting handles or slots in the doors. Electric door locks are operated by pressing a small push button.

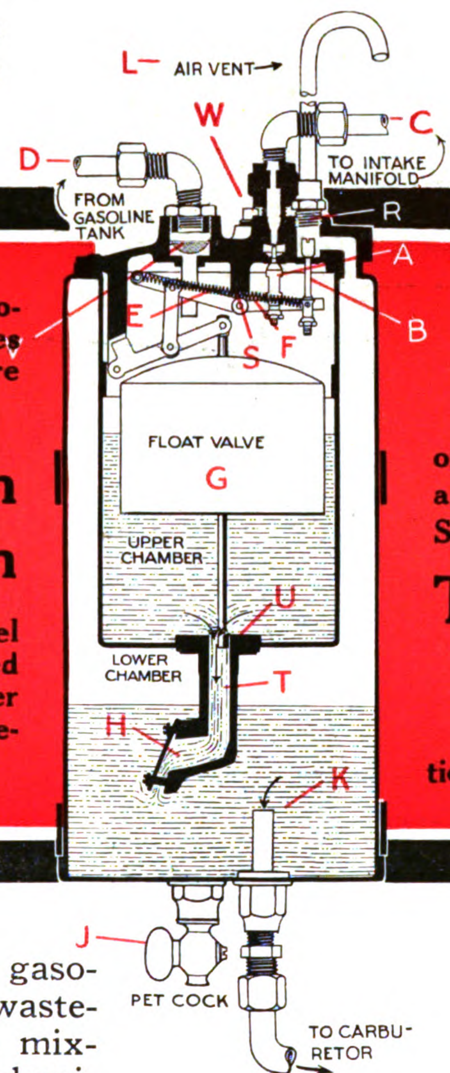
Stewart PRODUCTS

The STEWART Vacuum Gasoline System does away with all need of air pressure —eliminates hand and power pumps—air gauges and all air-tight connections.

It supplies an even flow of gasoline to the carburetor at all times regardless of what the grade may be.

This system enables car manufacturers to adopt the fashionable low-set streamline body. It enables them to do away with the somewhat dangerous, odorous and inconvenient gasoline tank in the cowl, as well as the gasoline tank awkwardly placed under the front seat.



NOW

$10

The STEWART Vacuum Gasoline System absolutely overcomes all the disadvantages of pressure and gravity feed systems.

Stewart Vacuum Gasoline System

It soon pays for itself in the fuel it saves. In recent tests sanctioned by the A. A. A. it showed better than 15 per cent. increase in mileage per gallon.

Can be installed in an hour's time on any car, old or new, at any garage or at any of our Branches or Service Stations.

Try it on Your Car for 30 Days

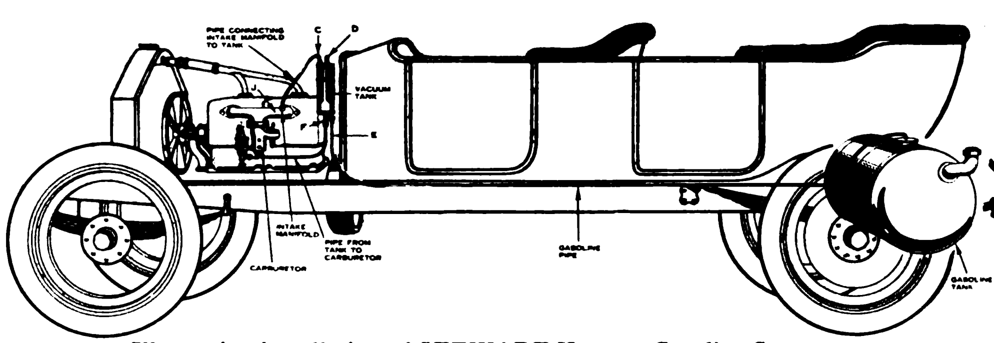
Comes complete with all connections. Write for full particulars.

There is no forcing of the gasoline through the carburetor wastefully—causing an over-rich mixture, a sluggish motor, or carbonization.

It works absolutely AUTOMATICALLY, requiring no attention whatever once it is installed.

Permits the gasoline tank to be put in its logical position in rear of car—placing the weight where it can be carried to best advantage, without detracting from the car's easy riding qualities.

DEALERS: Write for interesting Sales Proposition.



Illustrating installation of STEWART Vacuum Gasoline System, under hood on dash, or it may be mounted directly on motor.

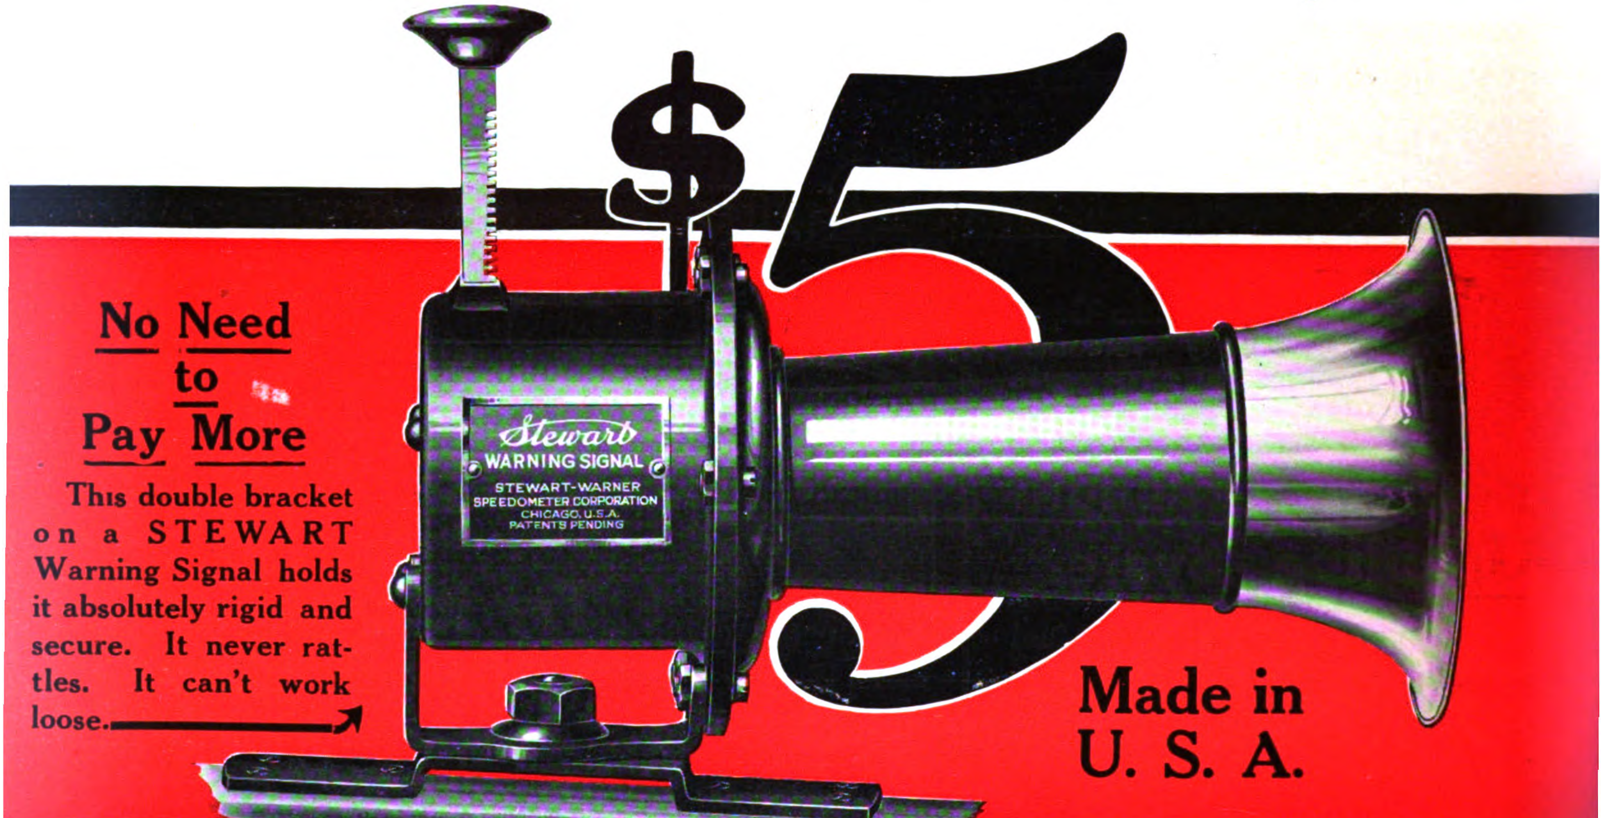
"Always on the Job"

PRODUCTS

Look for the name "Stewart" on all Stewart Products. It is a guarantee of Prestige, Quality, Service and Satisfaction.

This unprecedented price of $5.00 is only made possible by our policy of producing STEWART Products in enormous quantities.



The name "STEWART" has special significance when borne by a Warning Signal priced at $5.00—the lowest price a thoroughly high-grade hand-operated signal has ever reached. It adds authority to the statement that the STEWART Warning Signal in design, appearance, in material and performance, is the finest hand-operated signal built—regardless of price.

A swivel bracket enables the STEWART Warning Signal to be adjusted to direct warning blast **straight ahead, and fits top rail of car perfectly.**

The price is so small, the measure of quality so large for the reason that we require no separate plant to make and no separate organization to market this Warning Signal.

The STEWART Warning Signal is full-grown in every respect.

The length of the trumpet part of the horn is much greater than other makes of horn sold near its price, which means just so much more sound-carrying power.

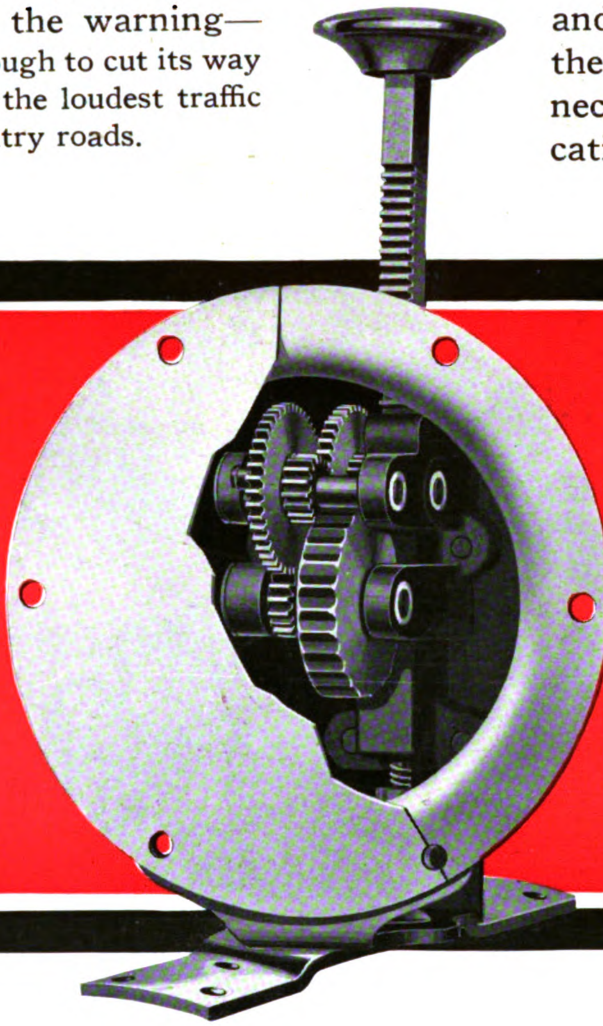
"Always on the Job"

Stewart PRODUCTS

The STEWART is the easiest operated Warning Signal sold. No effort is required, no feeling for a button or holding it down. The slightest touch of hand or elbow sounds the warning—sharp, penetrating and clear enough to cut its way through the rattle and roar of the loudest traffic and carry a mile ahead on country roads.

A felt pad oiler insures proper, CONTINUOUS lubrication to every bearing and wheel. It RETAINS the oil and eliminates the necessity of frequent lubrication.



Note the extra large Swedish steel diaphragm. One push of the plunger results in 192 distinct sound impulses against this diaphragm.

The sound produced is big-voiced and unsurpassed in penetrating and far-carrying qualities.

Stewart Warning Signal

Note the wide-faced, case-hardened gears. They are CUT, not stamped, from the highest-grade steel. They are carried in a frame with each gear mounted on double bearings.

No one-sided bearings are used, because of their being continually subjected to rack and wear.

Each bearing is mounted in a hardened steel bushing, insuring positive alignment, and exceedingly long life of service through the elimination of wear.

Built To Last

No part of this signal is soldered.

All parts are riveted or bolted to stay permanently — regardless of hardest usage.

30-Days' Free Trial

Put a STEWART Warning Signal on your car with the understanding if not satisfactory after 30 days' trial, full purchase price will be refunded. Furnished in handsome black enamel and nickel or black and brass finish.

DEALERS: Our 30-Day Free Trial makes a sale out of every inquiry.

It costs Nothing to operate

The STEWART Warning Signal is a self-contained unit dependent upon neither batteries, wires, nor connections of any kind. It has no short-circuits, loosened connections or weakened batteries to contend with. It is on the job all the time whether your batteries are or not. It does not drain current from the lighting and starting system. You pay for a STEWART Warning Signal but once. Its first cost is final. Its upkeep is nothing.

Ignition Advice For You

A good ignition system is a necessary part of every engine. Batteries alone, or as a part of another system, cannot be expected to retain that essential feature of absolute reliability which an ignition system should have.

If your engine is fitted with a good magneto, you obtain your ignition current from a mechanical source, a source that practically has perpetual life, a source that cannot be made inactive by ordinary damage, nor even by forgetfulness. It is not affected by heat or cold, by rain or snow, by continuous or intermittent use.

Ignition is a factor too important to slight. It should be given more than passing consideration or comment. It should be investigated as closely and as carefully as the engine itself, for upon the ignition system the ability of the engine depends. In fact, the whole car, your comfort, your pleasure, everything depends upon the ignition system.

Don't select "any ignition"; don't be misled by such broad terms as "high tension", "jump spark", or "magneto"—insist that you be given a dependable, no-worry system—a Bosch Magneto.

BE SATISFIED | *No one ignition system is used as universally as the Bosch Magneto* | **SPECIFY BOSCH**

K.P. Foot Rest Heater

It does seem foolish that a gasoline engine should be generating so much heat and let it all go to waste, while the passengers in the tonneau shiver with the cold.

Everybody appreciates the foolishness of that situation and realizes at a glance how simple and practical the K.P. FOOT REST HEATER is in the way it makes use of an otherwise waste commodity.

The K.P. is noiseless, odorless and expenseless. It is a handsome ornament in a car, for it looks infinitely better than the ordinary foot rest. Its regulating valve makes it easy to control by the passenger. It is easily attached. Furnished in lengths to fit any car, and made up in oxidized, nickel-plated or brass finish.

The price is $25 (f.o.b. New York), including all parts for attachment.

The dealer who has put it on display has found that it is as near a self-selling device as he could handle.

Now is the time to sell them.

Now is the time buyers want them.

Now is the time you should handle them.

J. M. Shock Absorber

They are the only really perfect shock absorbers built. They were the first of their kind, and have always maintained the highest conceivable standard of materials and construction.

The J. M. SHOCK ABSORBER business is the kind of business any highly reliable dealer is proud to have. "J M" stands for the best in shock absorbers and when a man buys this kind at a legitimate price which gives a reasonable profit to the dealer, the J. M. Shock Absorber Company stands behind them with its nation-wide service and its responsible guarantee.

The J. M. is now produced for cars of every size and type. Altho the J. M. famous Twin type, shown at the top, has proved itself supreme for large cars, yet we have produced other models which exactly meet the needs of lighter weight cars.

Type 3
J. M. Ford

The Ford J M Type 3 (shown below) has established its reputation as the greatest of all Ford Shock Absorbers. It is not the cheapest but it is the least expensive in the long run. It assures real comfort to all Ford owners and it lives as long as the car. Has a unique sliding tube container and is self-oiling. Illustrated pamphlet "P" tells all about it.

NOW NEARLY READY. A NEW TYPE J M FOR OVERLAND AND SIMILAR CARS

This absorber meets the demand for cars of not over 3500 pounds. It is based on J M principles, has J M construction and efficiency throughout. For Overland, Buick, Hupmobile or any car (except the Ford lighter than 3500 pounds) this is *the* shock absorber.

Write to-day for full details on this J M Type Z-2.

DREDNAUT
TRADE MARK
Motor Cloths

The Largest Manufacturers in This Line

There isn't any class of material made that is subjected to more severe service than the fabric used in automobile tops. In order to give satisfaction it must retain its appearance of newness permanently, without fading, stretching, rotting or losing its waterproof qualities, in spite of continuous exposure to sun, wind, rain, snow and dampness. None but the best can stand these conditions.

Chase Auto Top Fabrics Are Most Reliable

We are the largest and oldest manufacturers in the country engaged in this line. Every yard is made in our mills and we have the largest output of any manufacturer. With fifty years of manufacturing experience, we have specialized on the making of top fabrics for more than thirty years. No other maker is so well equipped to produce quality and reliability. No other maker has the facilities to compete with us in price, on fabrics of equal quality.

For Permanent Satisfaction, Specify Chase Fabrics

CHASE LEATHER

The finest substitute for genuine leather now on the market. Best in appearance, durability and wearing qualities. Our "Galloway," "Gibraltar," "Buckskin" and "Imperial" brands are especially popular in the automobile trade.

CHASE MOHAIR, LUSTRE TOP AND SLIP COVER CLOTHS

Unexcelled in quality—complete in assortment.

Drednaut Motor Cloths

Under this brand we market the finest rubber fabrics known in the trade.

CHASE MOTOR ROBES

The Chase Line of Motor Robes is unexcelled in assortment, variety and novelty of patterns and qualities. We have manufactured and sold more automobile and carriage robes than any other one organization in America.

Chase Mohair Body Fabrics

Something new and distinctive. Will wear a life time. You should know about these when considering your upholstering proposition.

The Thomas B. Jeffery Company
Jeffery
Kenosha, Wis. U.S.A.

The **Jeffery** Chesterfield Six is not in competition with low-priced cars. It is not in competition with other medium-priced cars. **It is in competition with the highest-priced cars in the world.**

The Jeffery Six and

Disregard price and consider that the **Jeffery** Chesterfield Six is equipped with the Bijur Starting and Lighting System in use by the foremost cars of the world;

—that it is the only car in the United States in its price class having a four-speed transmission;

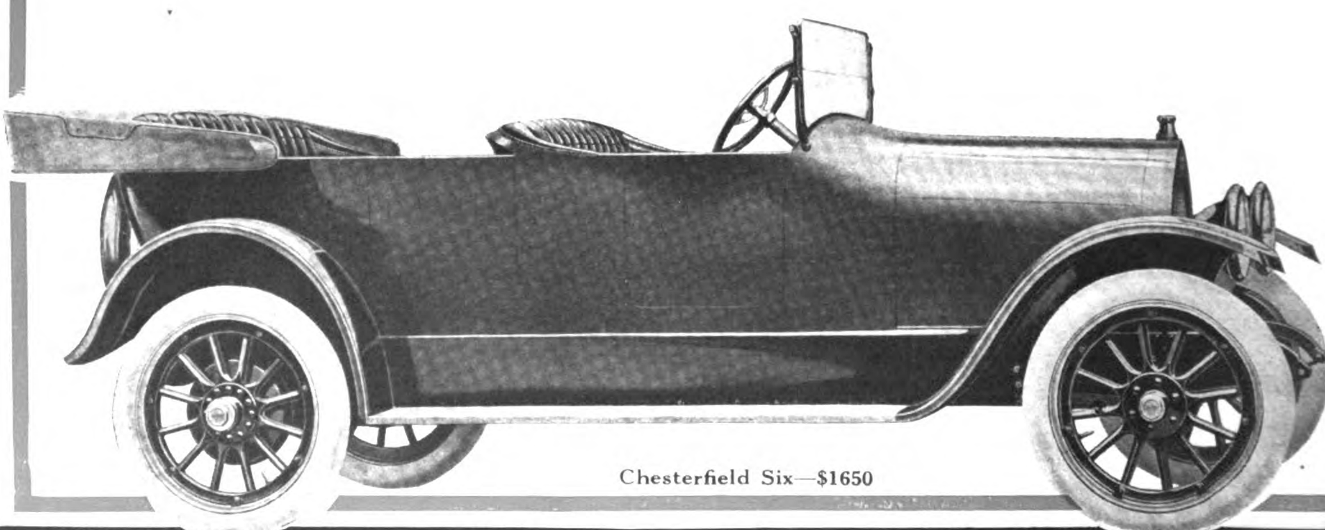
—that its worm drive is a type used exclusively on the finest electrics, and finest trucks and the best makes of foreign cars, but, with no important exceptions, on no other American car;

—that its finish—requiring 22 operations—is unsurpassed on any car here or abroad;

—that it has Tungsten steel valves five times costlier than the other kind, 3-plate dry disc clutch, imported annular bearings throughout, Bosch ignition throughout, New Model Stromberg carburetor, Stewart vacuum gasoline feed, Cantilever springs, Daimler leather coupling, Spicer universal joints, Waltham clock, and every refinement in the way of equipment.

Consider that these are actually specifications of cars in the four or five thousand dollar price class yet obtainable in the medium-priced **Jeffery** Chesterfield Six selling at $1650.

See the complete line of **Jeffery** Cars at the Shows, New York, Grand Central Palace, Space A31, or at Chicago, Coliseum, Space C3.



Chesterfield Six—$1650

Something like a thousand dollars would have to be added to the price of the **Jeffery** Six-48, if this car were made in small quantities and saddled with heavy selling expenses.

Chesterfield Six-48

The **Jeffery** Six-48 is beyond question the biggest $2400 worth of thoroughly high grade motor car obtainable on the market today.

It meets the demand of the man who wants a larger car than the Chesterfield Six—a car built to the **Jeffery** Standard of Quality—generous in size, luxurious, comfortable, easy-riding and durable as cars in the four and five thousand dollar class, yet exceedingly economical in operation.

Although a full-grown seven passenger car, it weighs but 3700 pounds and delivers remarkable mileage per gallon of gasoline.

The power plant is a 3¾ by 5¼ high-speed—high-efficiency motor with cylinders cast in pairs.

Due to its 48-H. P. power plant, it is as "quick on its feet" as the smaller **Jeffery** models. An ideal car for both city driving and long touring purposes.

The wheel base of this car is 133½ inches, and the tires are 36 by 4½, on demountable rims.

Finest materials are used as in other **Jeffery** models and the equipment is complete in every detail.

All prices f. o. b. Kenosha.

DEALERS: Jeffery Cars at their price offer the greatest opportunity in the field. See us at the Shows or write direct for detailed information.
